Attention: TSCA Section 8(e) Coordinator:

[redacted] hereby submits the attached documents pursuant to the TSCA Section 8(e). This is the summary and evaluation conducted by Dr. Gunter Oberdorster with results of inhalation toxicity test performed by [redacted] on carbon fiber (CAS#7440-44-0, manufactured by [redacted]. Since the raw material of the carbon fiber used the mesophase (anisotropic) pitch, the carbon fiber is classified into a mesophase pitch based carbon fiber. The form of the carbon fiber is a short fiber; the diameter was 1-2 micrometers.).

Sincerely,

8EHQ-04-15578

Subchronic Carbon Fiber Inhalation Study in Rats

[redacted]

January 2004

Subchronic Carbon Fiber Inhalation Study in Rats

1. Fiber Sample

Since the raw material of the carbon fiber used the mesophase (anisotropic) pitch, the carbon fiber is classified into a mesophase pitch based carbon fiber. The form of this carbon fiber is a short fiber; the diameter was 1-2 micrometers.

2. Carbon fiber biopersistence

2-1. Design

2-1-1. Target Exposure Concentrations

The dose levels will be adjusted (if technically feasible) in according with the following criteria:

Group	Test Item	Exposure Concentrations
1	Filtered Air	-----
2	Carbon Fiber	15 mg/m3

Air Control Group (Group 1): Rats will be treated with filtered air under the same conditions as animals exposed to fibers.

2-1-2. Allocation

All animals will be allocated to lung sampling for possible lung burden evaluation.

Sacrifice Time Point	GROUP 1 Air Control	GROUP 2 CARBON FIBER
1 Day	1 – 5	16 – 22
3 Days		23 – 29
14 Days		30 – 36
30 Days	6 – 10	37 – 43
90 Days	11 – 15	44 – 50
Reserve animals	51 – 55	

2-2. Evaluation of biopersistence results

A five-day inhalation study in rats with carbon fibers was performed at RCC (Basel, Switzerland) in order to determine the biopersistence of the fibers retained in the lung.

The carbon fibers had a geometric mean length of 6.74 μm and a geometric mean diameter of 0.92 μm in the aerosol. Electron micrographic images showed that some of the fibers were hollow. The exposure protocol followed the guidelines in the EU for the measurement of fiber biopersistence. Exposure was for 5 days, 6 hours a day, at a concentration of 16 mg/m^3. The number of fibers longer than 20 μm was 92 fibers/cm^3 in the exposure atmosphere. Rats were exposed in nose only exposure tubes in order to minimize contamination of the fur. Groups of seven rats were sacrificed at days 1, 3, 15, 29 and 92 after exposure. The lungs were excised and weighed. After chemical digestion of the lungs, the fibrous and non-fibrous particles that had been retained in the lung at the different timepoints were collected on filters and their numbers were determined by scanning electron microscopy. Fibers were categorized according to their lengths and diameters, and results were expressed as number of fibers retained in the lung in the following categories: Total fibers; WHO fibers; fibers less than 5 μm long (<5 μm); fibers 15-20 μm long: fibers more than 20 μm long (> 20 μm); fibers more than 40 μm long (> 40 μm); and non-fibrous particles (< 1 μm; 1-3 μm; > 3 μm).

At each of the 5 sacrifice time points, the lungs of the seven rats were excised and stored frozen until digestion. The chemical digestion method was carefully evaluated and validated using lungs of control animals that were spiked with a known amount of carbon fibers. The fiber analysis was performed at GSA (Neuss, Germany) according to well established standardized counting protocols using scanning electron microscopy. No significant residues of lung tissues and no significant change of fiber surfaces was found after digestion, the retained fibers could well be characterized and counted.

Fiber retention in the lungs during the 92 postexposure periods shows a high dependency on fiber length. About 30% of the long fibers (> 20 μm) cleared very rapidly in this study over the first 2 weeks post exposure, and overall their retention halftime was 100 days. During this same time, the numbers of non-fibrous particles increased in the lungs, and also numbers of fibers < 5 μm in length were slightly higher on day 3, whereas fibers between 15 and 20 μm in length decreased continuously and disappeared from the lung with a retention halftime of 46 days. All fibers taken together were cleared with a retention halftime of < 60 days, which is consistent with effective alveolar macrophage mediated clearance. The fact that non fibrous particles, and to some degree

short fibers (< 5 μm), showed the above mentioned early apparent increase in the lung while the long fibers (> 20 μm) decreased, is consistent with a significant breakage of the long fibers during the clearance phase. The fragments of the broken long fibers then provide additional input into the short fiber and non-fibrous particle category, causing the observed increase over the first 2 weeks post exposure.

The most potent fiber size in terms of long term pathology, in particular with respect to a carcinogenic potential, are fibers longer than 20 μm. This well accepted concept of fiber toxicology is based on earlier pioneering studies which had shown that longer asbestos and glass fibers are the most potent ones for inducing lung tumors and mesothelioma. One reason for this is that fibers above a certain length can not be phagocytized by alveolar macrophages. These cells are present in the alveolar spaces of the lung and eliminate (clear) foreign materials effectively, provided this material is small enough to be taken up by these cells. Since the diameter of alveolar macrophages is between 12 (rats) to 20 (humans) μm, fibers longer than 20 μm are unlikely to be cleared by these cells and are therefore most likely to interact with target cells in the lungs.

In this study, breakage of carbon fibers appears to be important for the overall reduction in numbers of long fibers in the postexposure phase resulting in the elimination of the fiber category with the highest carcinogenic potential. The resulting shorter carbon fibers and non-fibrous carbon particles can be effectively cleared by alveolar macrophages. Indeed, the retention halftime of the non-fibrous particles in this study – after the initial increase – is ~60 days, and for the other fibers shorter tan 20 μm it is even less than 60 days. These values are within the range of 50–70 days, which are normal retention halftimes in rats to clear particles and short fibers of low toxicity contained in alveolar macrophages out of the lung.

The decrease of long fibers postexposure is statistically significant. Figure 1 shows the retention of the long carbon fibers (> 20 μm) as found in the study. In addition to the individual data points, the retention curve is plotted, showing a monoexponential decay. A compartmental analysis was performed to determine the statistical significance of the long fiber retention. For a single compartmental model, a statistically significant slope of 0.00647 (Standard Error: 0.00174) is calculated. The corresponding retention half time is 107 days for fibers longer than 20μm. There is also some evidence for a second compartment, but not enough data for a more precise.

According to the new testing guidelines of the European Union (EU) for synthetic vitreous fibers, long fibers (> 20 μm) of a new fiber product should be cleared from the rat lung with a halftime of 10 days or less in order to avoid being labeled as a potential carcinogenic fiber. The guidelines are specific for glassfibers, and there are as of yet no data to suggest that they should

apply to carbon fibers. Since elemental carbon is insoluble in the lung or in lung cells one would expect that long carbon fibers have a very long biopersistence (halftime of several hundred days). However, it appears that a significant breakage rate makes long carbon fibers smaller and accessible to normal lung clearance via phagocytic cells resulting in the halftime of 100-107 days. Thus, one could hypothesize that it is likely that no adverse effects from long carbon fibers will occur, unless very high lung burdens are present which overwhelm the alveolar macrophage clearance function due to overloading of the macrophages by large numbers of shorter carbon fibers.

This hypothesis is supported by results of an earlier short term carbon fiber study which showed that carbon fibers do indeed not cause more inflammation in the lung than a glass fiber that did not induce lung tumors in a previous chronic rat inhalation study . If the low inflammatory potency of this carbon fiber is confirmed in an inhalation study of longer duration, it would be strong evidence that these carbon fibers should not be categorized according to the EU rule with respect to the requirement of a 10 day retention halftime for long fibers.

In that earlier 5 day inhalation study with carbon fibers it was found that the inflammatory response in the lung induced by a similar lung burden of retained carbon fibers and MMVF-10 (a glass fiber which did not induce tumors in a chronic inhalation study) was the same: There was only an initial slight inflammatory response in both fiber groups which returned to baseline level by 10 days postexposure; this was in contrast to amosite asbestos which induced a significantly greater and lasting inflammatory response and which was used as a positive control in that earlier study. (Fig. 2) However, since this previous study was a short term exposure (5days inhalation) only and since results of a longer term subchronic inhalation exposure to carbon fibers are lacking, a final statement regarding the inflammatory or toxic response of carbon fibers can not be made at this point. It is conceivable, though, that the relationship between carbon fiber bio-persistence and lung toxicity is different for carbon fibers on the one hand and for glassfibers and asbestos on the other hand.

Thus, overall evaluation from the biopersistence study is that long carbon fibers are most likely cleared from the rat lung by breaking down to smaller fragments, which in turn can be cleared by normal clearance mechanisms through phagocytosis by alveolar macrophages. However, some long fibers (>20μm) may persist longer. Whether this fraction of the long carbon fibers, in combination with the shorter fiber fragments in the lung, can cause adverse effects needs to be determined in a subchronic inhalation study.

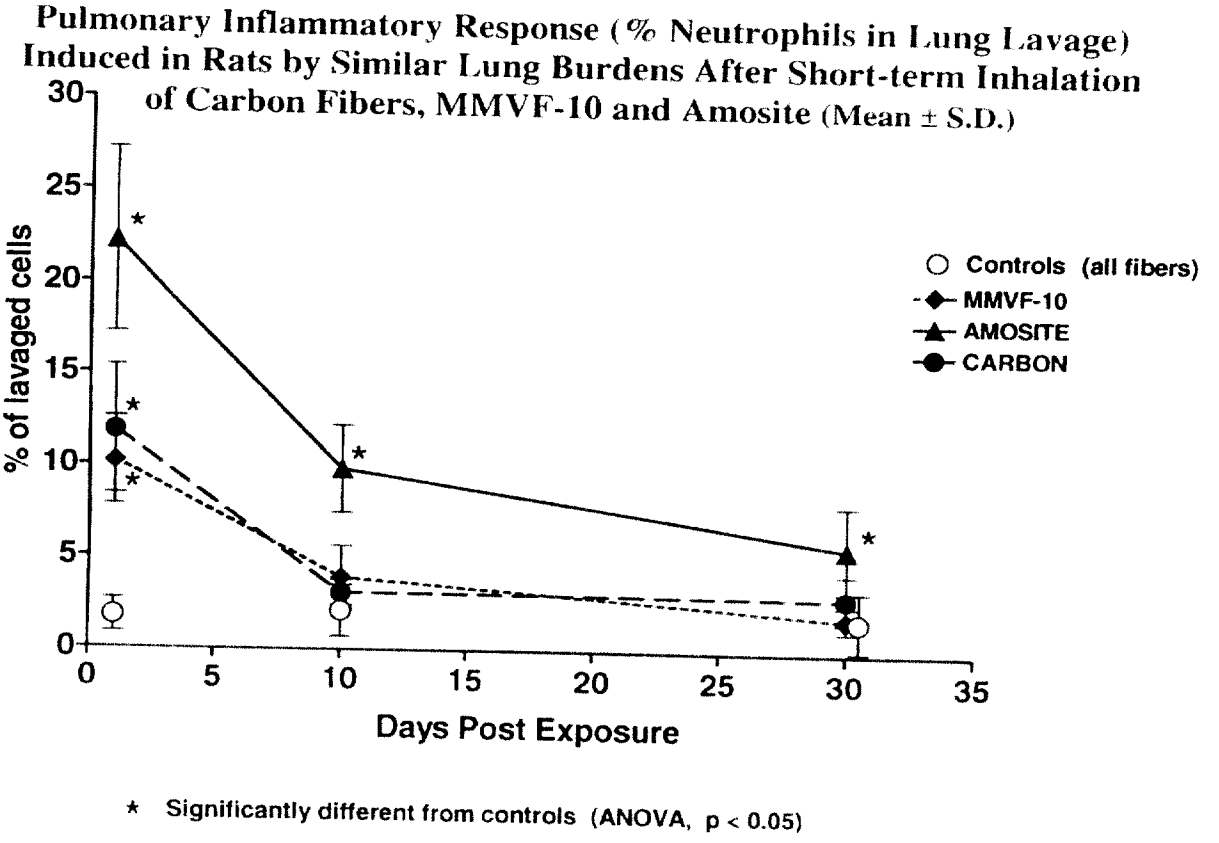

Figure 2. The pulmonary inflammatory response after short-term inhalation

3 Subchronic Carbon Fiber Inhalation Study

3-1. Design

A subchronic inhalation study in rats was performed for three dose groups of the carbon fiber sample. The 3 months exposure period was followed by a 3 months postexposure observation period. The rats were exposed 6 hours per day, 5 days per week for 3 months to a fiber aerosol concentration of 15, 50 and 150 fibers/ml (fiber length > 20µm). Within a 3-month observation period after end of 3 months exposure the rats were sacrificed at different intervals (see under Table1). The guideline of the European Commission ECB/TM 16(97) rev. 1 was used.

Table 1. List of investigations in the subchronic inhalation study
Exposure was terminated after 3 months; subgroups were kept for further 3 months for post-exposure investigations

Investigation	Test required after start of exposure [months]	Group	Number of animals per group for single investigation	Consecutive number of animals per group scheduled for investigation
Lung burden of test fibers	3 4 5* 6*	1-4	5 [a]	1-5 6-10*: 11-15*
Bronchoalveolar lavage	3 4 5 6	1-4	5	16-20: 21-25: 26-30
Histopathology/ BrdU	3 4 5 6	1-4	5	1-5 6-10 11-15
Reserve animals		1-4	2	31 32

* Lung burden analysis at 4 5 and 6 months optional

[a] The left lung lobe of animals scheduled for fiber burden analysis will be used for histopathology.

The study design is shown in Table 2

Table 2. Study design of the subchronic inhalation study, followed by a 3 months observation period

Exposure group	Group No	Fiber (Length>20µm) concentration (F/ml)	Gravimetric concentration* (mg/m^3)	Number of animals
Control (filtered air)	1	-	-	32
Carbon fibers low	2	~ 15	~ 2.5	32

Total				138

* Estimation based on SEM analysis of pretest for aerosol generation

3-2. Method

3-2-1. Histopathology

Conventional histopathological examination including fibrosis scoring (H&E staining and Masson-Trichrome staining) was performed on the left lung lobes and trachea (H&E staining only) of animals listed in Table 2. The McConnell-Wagner fibrosis scoring system (McConnell et al. 1984) was used. Additionally the EPS evaluation system including scoring for collagen deposition at the bronchiolo-alveolar junction (Annex in ECB/TM/16(97) rev, 1) was used. A quantitative evaluation of fibrosis using a morphometric method according to the criteria from J. Davis, IOM, Edinburgh was also done.

The Wagner scoring system is from grade 1 to 8, and grade 4 correspond to evidence of early interstitial fibrosis. The EPS system includes grade 0 to 5 and grade 2 is corresponding to evidence of early interstitial fibrosis.

3-3. Results

3-3-1. Concentration and Fiber Size Distribution in the Aerosol

The aerosol concentrations were measured by SEM. The means and standard deviations of the fiber and particle concentrations in the aerosol samples of the three exposure chambers are summarized in Table 3. The size distribution of the aerosol samples is presented in Table 4 .

Table 3. Numerical and gravimetric concentration of fibers in the exposure chambers

3-3-3. Bronchoalveolar Lavage

During the recovery period bronchoalveolar lavages (BAL) were performed on 5 rats per group and sacrifice date (at the last sacrifice date 6 rats for the control group and 7 rats for treatment group were used). The following biochemical parameters were measured in the supernatant of the bronchoalveolar lavagate: lactic dehydrogenase (LDH), β-glucuronidase (ßGL) and total protein. The results are summarized in Table 6. The results of the differential cell count are presented in Table 7.

3-4. Evaluation of subchronic results

---- Comparison of Carbon Fiber (Mesophase Pitch based Carbon Fiber) and MMVF-21 (Stonewool, Not carcinogenic in Rats), E-Glass (Microfibers, Durable Glass Fiber, carcinogenic in Rats) ----

The following paragraphs summarize the significant findings in terms of differences between carbon fiber and two other vitreous fibers which had previously been tested by the Fraunhofer Institute according to the same protocol. In my interim evaluation of this study, I had pointed out that the results of this carbon fiber subchronic rat inhalation study with respect to the inflammatory lung lavage parameters LDH and protein did not show a significant difference between MMVF-21 or E-glass and carbon fibers. Analysis of the cell proliferation data was still not done at that time.

After the statistical analysis of the cell proliferation assay has now been performed, it showed that at equal lung burdens of long fibers the carbon fiber exposed rats had induced significantly greater effects on bronchiolar cell proliferation but not on parenchymal (alveolar) cell proliferation. This distinction is important since in rats the alveolar Type 2 cells are the precursor cells for lung tumors, but not the bronchiolar cells. The statistical analysis of these results was performed by comparing those animal groups of the different fiber studies which had the same lung burden in terms of retained fibers longer than 20μm at the end of exposure. These long fibers are the fibers with the greatest carcinogenic potential. Thus, based on the retained fiber lung burden at the end of exposure the following groups were compared: Carbon low *vs.* E-glass low *vs.* MMVF-21 medium; carbon medium *vs.* E-glass medium. Comparisons between others groups cannot be made since the retained lung burdens are too different, as can be seen in the Table 10 below. Since the parenchymal cell labeling index did not show significant differences between the carbon fibers and the other fiber types, only the results of the Tukey test for bronchiolar cell labeling at 15 weeks post-exposure are summarized in Table 11. As is shown there, the E-glass low and carbon low groups are not significantly different from each other, whereas MMVF-21 mid-dose shows significantly lower proliferation than carbon low, but was not different from e-glass low; E-glass medium showed significantly lower bronchiolar cell proliferation than carbon medium. There was one additional significant difference between E-glass medium and carbon medium at 8 weeks post exposure, where E-glass again was significantly lower than carbon.

A surprising finding from comparing the carbon fiber results with the MMVF-21 and E-glass fibers is a significantly lower induction of inflammatory cells (neutrophils) in the lung (analysis of lung lavage cells) by carbon fibers compared to E-glass and MMVF-21 (figure1). This will be addressed below.

With respect to the retention of carbon fibers in the lung there is a dose-dependent increase of the retention halftime for fibers >20 μm (Table 12) from about 250 days for the low dose to about 500 days for the mid-dose and more than 1000 days for the high dose carbon fibers. This needs to be compared with retention halftimes for E-glass of about 60 days for all doses and for MMVF-21 of about 30 days for the low and mid-dose and 140 days for the high dose. Despite these long retention halftimes for carbon fibers, there is little accumulation of these fibers in the lymph nodes at 15 weeks post-exposure (Table 13), ranging between 0.3 and 0.4% for fibers greater than 20 μm long of the 3 dose levels, so there is no dose-dependent increase in that endpoint. For shorter fibers, there is a somewhat greater lymph node accumulation between 1.4 and 2.2% (except at the high dose for fibers less than 5 μm where the value is 7.1%). Unfortunately, no respective data for MMVF-21 and E-glass are available, but a subchronic study with amosite also conducted by the Fraunhofer Institute, showed lymph nodal retention for fibers longer than 20 μm to be lower (about 0.1%), and for all fibers it was also lower (0.4%) at 15 weeks post-exposure.

Thus, the long retention halftime in the lung and the translocation of carbon fibers to the lymph nodes point to a long biopersistence of carbon fibers in the lung accompanied by some translocation of the fibers to the interstitium. It is surprising that despite this long biopersistence and interstitial translocation, no increased fibrotic responses in the lung have been seen. It appears that E-glass, indeed, shows a greater fibrotic score than carbon at 15 weeks post-exposure (Fig. 2), however, this difference is statistically not significant.

The long biopersistence of carbon fibers and the increased cell proliferation of the bronchiolar cells make it difficult to predict what the outcome of a chronic study with respect to carcinogenicity would be. If we were dealing with a vitreous fiber, my prediction for a chronic rat inhalation study based on these findings would be that lung tumors will be induced in rats in a two-year study at the highest concentration. This prediction is mainly based on the long biopersistence of carbon fibers in the lung combined with a high dose effect, and less on bronchiolar cell proliferation, since bronchiolar cell proliferation is not viewed as indicating proliferation of precursor cells for lung tumors in rats.

However, recent developments in our thinking of using outcomes of short-term assays with fibers to predict long-term effects has undergone some changes, as can be judged from extensive ongoing discussions among a group of experts: The International Life Sciences Institute (ILSI) –

with sponsorship of the US-EPA - has convened two meetings and is preparing a document on "Testing of fibrous particles: Short-term assays". I am a member of this Working Group, and our group discussions focus on vitreous and asbestos fibers since this is the area where most experience and data have been accumulated. Organic fibers are viewed differently by this group, and carbon fibers are also viewed as outside this vitreous fiber category, and therefore require more data to conduct a final evaluation regarding carcinogenicity. Significant gaps need to be filled in order to understand better possibly different patho-physiological mechanisms for these types of fibers compared to vitreous fibers. These new developments in fiber toxicology *vis-à-vis* our well-established data set on the correlation between fiber biopersistence and adverse health effects for vitreous fibers have to be appropriately considered here. For this reason, I am hesitant to categorically predict that these carbon fibers are likely to be carcinogenic, which I would do if these results were from a biopersistent vitreous fiber. A key consideration should be that alveolar cell proliferation was not increased compared to vitreous fibers.

I will try to rationalize my response by drawing parallels to what we know about spherical carbon particles. Spherical carbon particles tested in long-term rat inhalation studies have been found to induce lung tumors only at concentrations which resulted in a phenomenon termed "lung particle overload". The same is true for any fibrous particle of low cytotoxicity, *e.g.*, TiO_2, which will induce lung tumors only in rats when an overload situation is achieved, but not in other rodents; for this reason, based on the animal data, TiO_2 specifically has been de-listed as a potential human carcinogen by EPA. Cytotoxicity of the particles is the key to differentiate potential carcinogenic compounds: When a cytotoxic particle such as crystalline silica (SiO_2) was tested in a long-term inhalation study in rats, it induced lung tumors at much lower concentrations than TiO_2 or carbon; and these SiO_2 concentrations clearly did not induce what is defined as "lung particle overload". Based on the animal experimental data and also on available positive epidemiological data from occupational expopsures, SiO_2 is characterized as a known human lung carcinogen.

Typical findings in positive (lung tumor-inducing) rat inhalation studies with particles are always the same, regardless of whether lung overload situations are generated with very high doses of more benign particles such as carbon and TiO_2 or with lower lung doses of a cytotoxic particle such as SiO_2: Chronic pulmonary inflammation, increased alveolar cell proliferation, interstitial fibrosis, lung tumors. In contrast, low lung doses of spherical particles of low cytotoxicity, such as carbon or TiO_2, do not induce these effects.

In the present subchronic carbon fiber inhalation study, the lung burdens of the low dose group (about 300 μg, Table 13) was clearly not in the overload range by mass, whereas the mid-dose (lung burden about 1.2 mg) and certainly the high dose (lung burden greater than 3 mg) were

in the overload range. Despite the high lung burdens in the mid- and high-dose carbon fiber groups, alveolar inflammation at one week post-exposure as judged by the percent of neutrophils in lung lavage, was significantly lower than that of MMVF-21 and of E-glass; this is inconsistent with what one would expect from a carcinogenic fiber. This inconsistency, indeed, may point to the fact that carbon fibers — as discussed presently within the afore mentioned ILSI Working Group — may interact differently with target cells in the lung than glass or asbestos fibers.

On the other hand, the significance of the increased bronchiolar cell proliferation at 15 weeks post-exposure may either indicate a potential for significant adverse effects, such as fibrosis, later on— although the fibrotic score was not significantly different from MMVF-21 — or may point to a "physiological" response in the conducting airways towards the carbon material. In the context of cell proliferation, it should kept in mind that parenchymal cell proliferation and pleural cell proliferation – which are more predictive for tumorigenesis by inhaled fibrous particles in rats - were not significantly increased against MMVF-21.

Overall, the outcome of this subchronic carbon fiber study clearly shows increased biopersistence of the carbon fiber compared to vitreous fibers, and increased bronchiolar cell proliferation at late timepoints post-exposure. The lung inflammatory response and the fibrotic score, in contrast, are less than would be expected from a persistent fibrous particle with fibrotic and carcinogenic potential. Given the present uncertainty among experts of a fiber working group on how to categorize carbon fibers based solely on the outcome of a short-term assay, a prediction regarding a carcinogenic potential can only be made with great caution, lacking data of a chronic carbon fiber study. Based on our present knowledge, it is my view that inhaled concentrations of carbon fibers which do not cause lung overload will not induce lung tumors in a chronic rat inhalation study. This means that carbon fibers seem to induce pulmonary effects similar to those of low cytotoxic particles. Accepting this concept and applying an adequate safety factor for human exposures to carbon fibers, workplace conditions can be created through appropriate surveillance and engineering conditions which do not exceed "safe" airborne concentrations.

SUMMARY AND CONCLUSIONS

General

The aim of the study was to investigate the intrinsic toxicity of carbon fibers with a mean diameter of about 1μm in rats after subchronic inhalation according to the protocol of the European Chemicals Bureau (ECB/TM 16 (97) rev. 1).

Rats were exposed 6 hours per day, 5 days per week for 3 months. The target dose was an exposure to 15, 50 and 150 fibers/ml at a fiber length > 20 µm. **Table 3** shows that these concentrations were reached. After exposure of rats to the test fiber no biological effects were observed except those in the lungs.

In the medium and high dose groups a statistically significant increase of the lung weight was observed up to 3 months postexposure (see **Table 6**). In the low dose group a significant increase was seen only at the first sacrifice date 1 week postexposure.

After 3 months of exposure the lung retention of WHO fibers in fibers per lung was about 13 x 10^6, 62 x 10^6 and 145 x 10^6 for low, medium, and high dose, respectively (see **Table 7**). The corresponding values for long fibers (length > 20 µm) were about 3.3 x 10^6, 10.8 x 10^6 and 31.5 x 10^6 for the three groups. The corresponding values for the retained mass of fibers (estimation from the number and size of fibers in the lung ash) in the lungs in mg/lung were 0.27, 1.1, and 2.8 for low, medium, and high dose, respectively. The estimated particle mass was less than 20% of the corresponding fiber mass in the lungs for all fiber groups.

After 3 months of recovery the WHO fiber concentration in the lungs decreased to 55%, 50% and 67% for the low, medium and high dose group, respectively. For the long fiber fraction with length > 20μm the corresponding data were 77%, 89% and 93% for the three dose groups. The elimination of fibers is slower in the high dose group compared to the low and medium dose group. Additionally the elimination of the long fiber fraction is much slower than for the WHO fiber fraction, which is different to the clearance behavior of man-made vitreous fibers. For most MMVFs a faster clearance was detected for the long fiber fraction compared to the WHO fiber fraction.

The effects on biochemical parameters (LDH and protein) in the bronchoalveolar lavage fluid (BALF) were statistically significant at the end of the 3 months exposure and at 8 and 15 weeks post-exposure for the high dose groups (**Table 11**). For the medium dose group the effect on protein was statistically significant and the effect on LDH was not significant for all sacrifice dates. For the low dose group only the protein was increased significantly only once at end of exposure. The effect on ß-glucuronidase was significant only for the high dose group at end of 3 months exposure but not for later sacrifice dates. For the low and medium dose group the small increase of ß-glucuronidase was not significant for all sacrifice dates.

For medium and high dose fiber groups a statistically significant increase of neutrophil PMN and a

reduction of the percentage of macrophages in the BALF was observed for all sacrifice dates, but PMN levels were lower for 8 weeks and 15 weeks postexposure (**Table 12**). There was also a significant increase in lymphocytes in the mid and high dose groups up to 3 months postexposure. No significant effect was seen in the low dose group.

Histopathology

At the termination of the 3-month exposure period, very slight to moderate morphological changes were diagnosed in the lungs (**Table 15**). These changes included alveolar macrophage aggregation and/or microgranulomas at the bronchiolo-alveolar junction. At the end of exposure evidence of early interstitial fibrosis was detected for 2 rats of the medium dose group and for all 5 rats of the high dose group (**Table 15**). At 8 and 15 weeks postexposure this effect decreased to one rat of the medium dose group, but was retained at 5 rats for the high dose group.

The cell proliferation was enhanced at end of exposure in the high dose group for the bronchiolar epithelium, for alveolar parenchymal cells and for pleural cells, in the medium group for the bronchiolar epithelium and for alveolar parenchymal cells, and in the low dose group only for the bronchiolar epithelium (**Table 16**).

For the alveolar parenchymal cells the increase of cell proliferation persisted at significant levels for the high dose group up to 3 months, but for the medium dose group it was no longer significant at 3 months postexposure. For the cell proliferation of the bronchiolar epithelium the increase retained significant up to 3 months postexposure for all treatment groups. This effect corresponds to the histopathological finding of bronchio-alveolar hyperplasia, which is a cellular response to fiber deposition and retention at the bronchioalveolar epithelium. This is an protective effect to increase the mucus production for enhancement of clearance of fibers in that region.

Overall assessment

In a previous study at Fraunhofer ITEM (Bellmann et al, 2003) three other fiber types (E-glass microfibers, stonewool MMVF21 and the biosoluble Calcium-Magnesium-Silicate [CMS] fiber) were investigated in a 90 day inhalation study using the same protocol (ECB/TM 16(97) rev. 1).

The effects for different parameters are plotted versus the retained number of long fibers (length>20μm) in Figures in Appendix 10.

The results of comparison the effects of carbon fibers to that of E-glass, MMVF21 and CMS are summarized in **Table 17** (see page 61).

Datum der Inspektion / Date of Inspection
(Tag.Monat.Jahr / day.month.year)

25. – 27. November 2002

Die/Der genannte Prüfeinrichtung/Prüfstandort befindet sich im nationalen GLP-Überwachungsverfahren und wird regelmäßig auf Einhaltung der GLP-Grundsätze überwacht.

The above mentioned test facility / test site is included in the national GLP Compliance Programme and is inspected on a regular basis.

Auf der Grundlage des Inspektionsberichtes wird hiermit bestätigt, dass in dieser Prüfeinrichtung/diesem Prüfstandort die oben genannten Prüfungen unter Einhaltung der GLP-Grundsätze durchgeführt werden können.

Based on the inspection report it can be confirmed, that this test facility / test site is able to conduct the aforementioned studies in compliance with the Principles of GLP.

1 PREFACE

1.1 General Information

Fraunhofer ITEM Study No:	02G02022
Test Facility:	Animal Room No. T1.030a Room T1.108/109 (Laboratory) Room T1.07 (Necropsy area)
Test Item:	Carbon fibers (lot P-173)
Fraunhofer ITEM Study Director:	Dr. rer. nat. B. Bellmann
Sponsor's Project Monitor:	Prof. Dr. G. Oberdörster
Study Initiation Date:	August 14, 2002
Experimental Starting Date (Start of animal exposure):	August 15, 2002
Experimental Completion Date Last date on which data are collected directly from the study:	September 29, 2003
Study Completion Date:	September 30, 2003

1.2 Guidelines for Conduct of Study

This animal study was conducted in compliance with the Principles of Good Laboratory Practice (OECD January 21, 1998 and German Chemicals Law § 19a Appendix 1 pp. 2119-2129, June 28, 2002).

The study followed the regulations of the German Animal Protection Law (Tierschutzgesetz of May 25, 1998).

1.3 Study Staff

Study Director:	Dr. rer. nat. B. Bellmann
Deputy Study Director:	Dr. rer. nat. O. Creutzenberg
Aerosol Scientist:	Dr. rer. nat. G. Pohlmann
Laboratory Animal Veterinarians:	Prof. Dr. med. vet. C. Dasenbrock
	Dr. med. vet. Th. Tillmann
Biochemist:	Dr. rer. nat. O. Creutzenberg
Clinical Chemist:	Prof. Dr. rer. nat. W. Bartsch
	Dr. med. vet. T. Hansen
Pathologists:	Dr. med. vet. H. Ernst
	Dr. med. vet. S. Rittinghausen
Quality Assurance:	Dr. M.B. Ketkar

2 GENERAL STUDY INFORMATION

2.1 Objective

The objective of this non-clinical health and environmental safety study was to investigate the intrinsic toxicity of carbon fibers with a mean diameter of about 1 μm.

Strategies

The biological activity (inflammatory, cell proliferative and fibrotic potential) of carbon fibers was investigated after subchronic inhalative exposure in rats.

The investigation followed in principle the preliminary guideline of the European Chemicals Bureau (ECB/TM 16 (97) rev. 1) for the investigation of the toxicity of Synthetic Mineral Fibers (SMF) in rats after subchronic inhalation. The results can be compared to previous studies conducted at Fraunhofer ITEM with different SMF and with amosite asbestos using that protocol (Fraunhofer ITA, 2001, Bellmann et al., 2001, Brown et al. 2001, Bellmann et al., 2003).

2.2 Overall Design

A subchronic inhalation study in rats was performed for three dose groups of the carbon fiber sample. The 3 months exposure period was followed by a 3 months postexposure observation period.

The rats were exposed 6 hours per day, 5 days per week for 3 months to a fiber aerosol concentration of 15, 50 and 150 fibers/ml (fiber length > 20μm). Within a 3 month observation period after end of 3 months exposure the rats were sacrificed at different intervals (see **Table 2**).

2.3 Primary Parameters

The endpoints at different post exposure dates included:

Body weight, lung weight

Bronchoalveolar lavage

- cell concentration (macrophages, neutrophils, eosinophils and lymphocytes)
- biochemical parameters (lactic dehydrogenase (LDH), ß-glucuronidase, and total protein)

Conventional histopathology of lung and cell proliferation measurement test (BrdU S-phase response assay).

Lung burden was analyzed in terms of the number and bivariate size distribution of fibers and particles in the lungs at end of exposure and at different time intervals after exposure. The half-time ($T_{1/2}$) for the elimination of fibers of different length fractions was calculated using fiber burden at 1, 8, and 15 weeks postexposure.

2.4 Method Guideline

The preliminary guideline of the European Commission ECB/TM 16(97) rev. 1 was used with the following modification:

A modified procedure for monitoring the aerosol concentration was used (see **5.2.1**).

3 TEST ITEM

The test item (carbon fibers, lot number P-173) was supplied by the sponsor along with all the necessary information. For the subchronic inhalation study about 200 g of sized test fibers (see **3.2**) were necessary. According to the preliminary EC guideline ECB/TM/16 for SMF the geometric mean diameter (GMD) of the fibers longer than 20 μm in the sized material should be as close to 0.8 μm as possible, for fibers with a density of about 2.4, if technically feasible. However since carbon fibers have a lower density (about 1.5) the GMD could be close to about 1.0 μm, if technically feasible. The sponsor is responsible for the correct identity of the test fibers.

The remaining test item was returned to the sponsor after end of exposure except a sample for storage in the archives of Fraunhofer ITEM.

3.1 Safety Protection, Storage and Handling

Routine hygienic procedures were followed to assure that there were no adverse effects on the health and safety of personnel handling the test fiber.

3.2 Sizing of the Bulk Material

The bulk commercial material obtained from the sponsor was shortened by milling in a Retch® mill. The milled material was used directly for aerosol generation. It was not necessary to use an aerosol separation technique for additional sizing. Previous experience suggested that a considerable fraction might be particles which do not fulfill the fiber definition. The amount of this fraction is dependent on the properties of the test fibers. The goal was to keep the amount of non-fibrous particles less or equal to 20% of mass.

The fraction of respirable fibers was characterized by analyzing the length and diameter of about 400 fibers.

3.3 Characterization of Test Fiber

The test fiber was characterized by a Scanning Electron Microscope (SEM, LEO-430, LEO Elektronenmikroskopie GmbH, Oberkochen, Germany).

A small fraction of the test fibers (about 0.1 mg) was suspended in 10 - 20 ml double-distilled water (containing 0.05% Tween 80). Then the suspension was sonicated (Sonorex RK 510H at 35 kHz and 225 W, Bandelin, Berlin, Germany) for about 30 sec and filtered onto a Nuclepore® filter (25 or 47 mm diameter, pore size 0.2 or 0.4 μm). The preparation of the SEM sample and the counting and sizing is described in section **3.4**.

3.4 SEM Analysis of Fiber Samples

The following procedure was used for stock fibers and fibers in aerosol samples and lung samples.

3.4.1 Preparation of SEM Samples

A part of the filter containing the fiber sample was mounted on an aluminum stub and sputtered (Balzers SCD 030, Balzers Hochvakuumtechnik, Wiesbaden, Germany) with about 30 nm of gold.

3.4.2 Counting and Sizing Rules (for aerosol and lung fibers)

The general guidelines provided by the WHO/EURO (World Health Organisation, Reference Methods For Measuring Airborne Man Made Mineral Fibers (MMMF), prepared by the WHO Regional Office for Europe, Copenhagen (1985)) was followed with the following additional procedures for synthetic mineral fibers.

3.4.3 Length and Diameter

Sizing of length and diameters were performed using a SEM at a magnification of at least 2000. All objects, which were seen at this magnification, were counted. Fibers crossing the boundary of the field of view were counted as follows. Fibers with only one end in the field were weighted as half of a fiber and fibers with neither of their ends in the field were not measured. Diameters of fibers which were seen at 2000 magnification were measured at full screen magnification (usually up to a magnification of 12,000). No lower or upper limit is to be imposed on either length or diameter. The length and diameter were recorded individually for each fiber measured so that the bivariate distribution could be determined. When sizing, an object was accepted as a fiber if the ratio of length to diameter was at least 3:1. All other objects were considered to be particles. There was no truncation in the measurements.

For aerosol and lung samples from length and diameter of fibers the mass was estimated assuming cylindrical geometry of fibers. A density of 1.0 g/cm^3 was used which resulted in the best correspondence between gravimetric aerosol concentration and SEM estimated aerosol concentration.

The results of the size distribution of the aerosol and lung samples are presented as percentile values and as arithmetic and geometric means and standard deviations. The aerodynamic diameter of fibers was calculated from length L, diameter D and density S (using A=2 x LN (L/D)) (Harris and Fraser, 1976) by:

$$Aer.D. = 1.5 * D * \sqrt{\frac{S}{\frac{0.385}{A-0.5} + \frac{1.230}{A+0.5}}}$$

3.4.4 Stopping Rules

Enough fields of view were counted for evaluation so that at least a total of 0.15 mm^2 of the filter surface (for 25 mm diameter) was examined. The following conditions were fulfilled:

1. Fibers: A size selected analysis using a minimum of 100 fibers per category for the 2 length categories ≤ 5 μm; and > 20 μm and a minimum of 200 fibers for the length category 5 - 20 μm was used. The distance between two fields of view for analysis was at least 10 fields. Sizing was stopped when 1 mm^2 of the filter surface was examined, even if the minimum number of fibers was not reached for a category. The raw data file contains the different values for the areas which were analyzed for the 3 length categories. The total number of fibers per filter was determined by

normalizing the surface area counted to the total surface area of the filter.

2. Particles: The recording of particles was stopped when a total of 100 particles were counted.

4 TEST SYSTEM

4.1 Animal Model

Male Wistar rats (strain Crl:WU) were purchased from Charles River Deutschland, Sulzfeld, Germany. The age of the animals at the start of exposure was about 8 - 9 weeks and the weight approximately 200-300g.

Rats were exposed to the test fiber by nose-only inhalation. For a period of 3 weeks prior to exposure animals were trained to become accustomed to nose-only tubes.

Wistar rats were recommended by an EPA workshop (Vu et al., 1996) for use in subchronic and chronic inhalation toxicity studies of fibers. According to protocol ECB/TM/16(97) rev. 1 the use of male Wistar rats is preferred.

4.2 Disease Screening

The animals were received as SPF rats (specific pathogen free). They were maintained under barrier conditions throughout the study, and a subgroup (10 rats) was included for Disease Surveillance. This Disease Surveillance included screening for the presence of antibodies to the following pathogens: Pneumonia virus of mice (PVM), Sialodacryoadenitis (SDA)/ Rat coronavirus (RCV), Mycoplasma pulmonis, Sendai virus (Parainfluenza-1 virus), Kilham rat virus (KRV),Reovirus type 3 (Reo3). The Disease Surveillance was performed at the start of the study, near week 13 and near the end of the study.

4.3 Acclimatization

The animals were allowed to adjust and become acclimatized to the Fraunhofer ITEM environment for approximately four weeks before starting exposure. Upon arrival, all animals were thoroughly examined including the skin and coat, eyes, ears, nose and body openings.

For acceptance of animals into the study the physical condition of the animals were checked by daily clinical observations in addition to the Disease Surveillance (see **4.2**). During this time animals were trained to become accustomed to nose-only tubes.

4.4 Randomization

The animals were allocated to groups on a body weight basis. Prior to the initiation of the treatment the animals were weighed, randomized and grouped by the PROVANTIS software (management of toxicology laboratory data, Instem Life Science System Ltd., Walton Industrial Estate, Stone, Staffs, ST 15 OLT, Great Britain, version 5.0.1). This process assured that the mean group body weights of rats within groups (see **Table 1**) were very similar, at that time.

4.5 Identification

To each animal in the study a unique four or five digit identification number was assigned. These four or five digits are necessary for data storage in the computer system. The number assigned was G0NN where G denotes the one or two digits (1-32) group number, 0 is a common separator and NN is the two digits (01-99) consecutive animal number. All data collected from an animal were filed under that number. Each animal was permanently identified by a metal plate containing the study number, the group number and the consecutive animal number on the cage corresponding to that identification number. The right ear of the animal was tattooed with the group number and the left ear with a two digit animal number.

4.6 Housing and Maintenance

Animals were housed in Makrolon® (polycarbonate) cages type III (37.5 x 21.5 x 20 cm, two rats per cage) and were maintained under barrier conditions. Cages and absorbing softwood bedding material (Altromin 3/4, Altromin International, Lage, Germany) were changed twice a week or more often when necessary. Drinking water from the Hannover city water supplier was offered ad libitum fresh weekly or more often when necessary in a Makrolon® bottle fitted with a stainless steel nipple top with a hole approximately 0.5 mm in diameter. As diet a commercial chow in pellet form was used, identified as "Altromin 1324 N spec. prepared", purchased from Altromin International, Lage, Germany. Diet was offered ad libitum fresh weekly or more often when necessary.

The temperature and the relative humidity of the animal room was monitored electronically and recorded on a continuous basis. The limits were set at 22 ± 2°C for temperature and 55% ± 15% for relative humidity. A 12-hour light/dark cycle was used for lighting controlled by an automatic timing device.

4.7 Disposal

Biological waste material including food, bedding, and other disposable materials generated in the animal facility were collected in a special container and disposed of in compliance with local, state, and federal regulations.

4.8 Daily and Weekly Observations

All animals were observed in their cages daily. Animals were also removed from the cages once a week (during exposure period twice weekly), and carefully examined for abnormalities.

4.9 Body Weight Data

Individual body weights were recorded to the nearest 0.1 g once a week up to 3 months and thereafter every 2 weeks throughout the study for all animals. All body weight data were collected using electronic balances, interfaced with a computer and programmed for direct on line data acquisition using the Provantis software (see **4.4**).

4.10 Data Collection and Documentation

Body weights, lung wet weights, weights of the lower half trachea, the BAL data and the histopathological findings were recorded as computer output and/or in bound laboratory notebooks. The reports of body weights, lung weights, LDH, ß-Glucuronidase, and total protein were produced by the Provantis software. The reports of histopathological investigations were obtained from PLACES software.

5 STUDY DESIGN

5.1 General Outline

The study design is shown in **Table 1**.

Table 1 Study design of the subchronic inhalation study, followed by a 3 months observation period

Exposure group	Group No.	Fiber (Length>20μm) concentration (F/ml)	Gravimetric concentration* (mg/m^3)	Number of animals
Control (filtered air)	1	-	-	32
Carbon fibers low	2	~ 15	~ 2.5	32
Carbon fibers medium	3	~ 50	~ 7.5	32
Carbon fibers high	4	~ 150	~ 25	32
Disease Surveillance				10
Total				138

* Estimation based on SEM analysis of pretest for aerosol generation

5.2 Aerosol Generation and Exposure

The test fiber was given to the rats by "nose-only - inhalation". For each nose-only exposure unit the fiber aerosol was generated by a high-pressure pneumatic disperser. The disperser was fed with the test fiber under computerized control, i.e. with feedback to the actual aerosol concentrations measured by an aerosol photometer (see **Fig. 1**). The photometer gave a scatter light signal which is nearly proportional to the particle concentration, if the particle size distribution is constant. The ratio between photometer signal and concentration was determined throughout the study by comparing to gravimetric and numerical fiber concentration.

The aerosol of the test fiber was neutralized by a Ni-63 source to reduce the charge on the fibers. The aerosol was given to the rats by a flow-past nose/snout-only inhalation exposure system which was used for previous fiber inhalation studies at Fraunhofer ITEM. In this system, the fiber aerosol is supplied to each animal individually, and exhaled air is immediately exhausted. The airflow to each animal was approximately 1 l/min which is calculated to be laminar. Therefore according to the protocol ECB/TM/16(97) rev. 1 it was not necessary to measure the oxygen concentration. The airflow, the temperature and the humidity were monitored continuously and were stored as 20 min. mean values.

The animals were restrained in Battelle type polycarbonate tubes; with this system animals in the supply tubes keep their noses close to airflow at the opening of the tubes. The exposure of animals was performed in identical exposure chambers of cylindrical shape, each housing up to 48 animals (3 levels for 16 animals each). Control animals were exposed in identical units to filtered air only.

The duration of exposure was 6 hr/day, 5 days/week for 3 months to three fiber aerosol

concentrations of about 15, 50 or 150 fibers/ml (fiber length > 20 μm). There was no exposure on October 3, 2002 which is a public holiday in Germany. The mean value of the fiber concentration was within +/- 10% of the target value (see **9.1**). Before starting the exposure of rats the aerosol concentration (gravimetric and number of fibers and particles) was tested to get an appropriate fiber concentration and to obtain information about the concentration of particles from begin of the study.

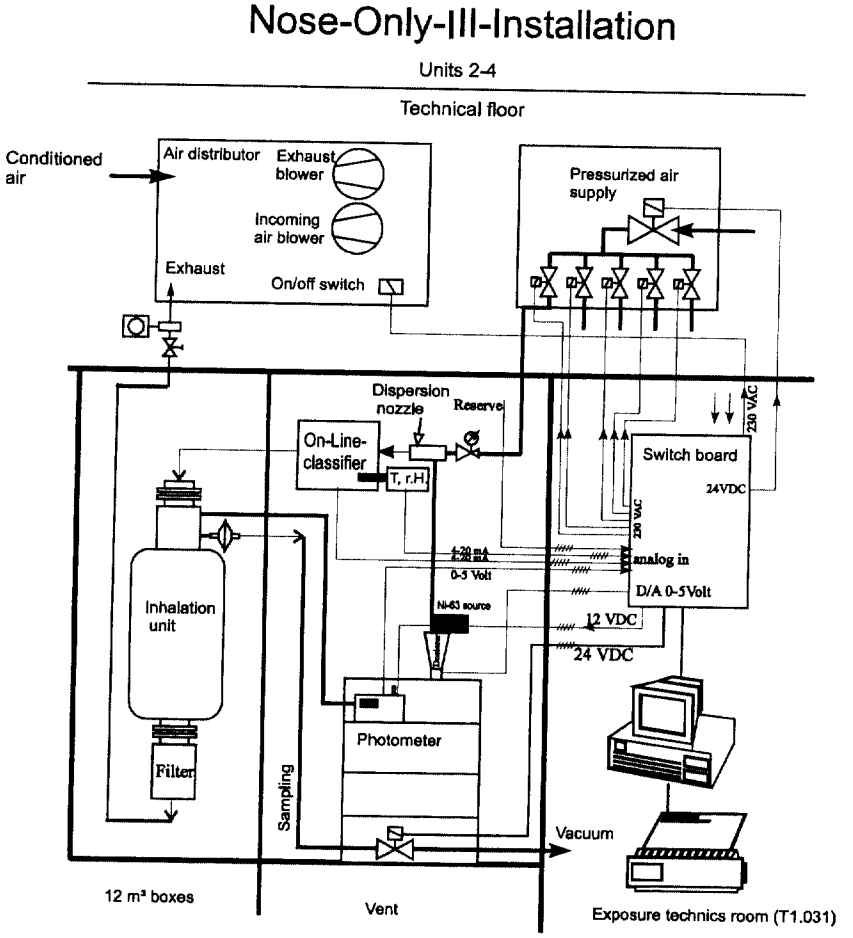

Fig. 1 Experimental set-up of nose-only inhalation system

5.2.1 Monitoring Aerosol Concentration and Fiber Dimensions

The aerosol was monitored (A) by an aerosol photometer (online), (B) by determination of numerical concentration (SEM analysis of filter samples) and (C) by determination of gravimetric concentration (weighing of filter samples).

The number of filter samples for gravimetric analysis (glass fiber filter, Sartorius) and for SEM analysis (Nuclepore filter, pore size 0.8 μm) was used according to the protocol ECB/TM16(97) rev. 1.

Two gravimetric samples per dose group and per exposure day were used.

For one filter the sampling time was about two hours and for the other filter sampling time was timely in coincidence with the sample for fiber counting. For fiber counting and sizing the filter sampling time

is dependent on the fiber concentration (20 to 60 minutes for the dose groups of the test fiber in this study). For the low dose group the filter load of the 60 min filter sample was not sufficient for a precise weighing, therefore only the about 2 hour sampling time was used timely in coincidence with the sample for fiber counting.

For SEM analysis one filter per exposure day and per exposure group was sampled. In the first week all five filters per exposure group, in the following weeks 2 filters were analyzed. The fiber load on the aerosol filter may not be equally distributed. For this reason fibers were resuspended in water (containing 0.05% Tween® 80) and filtered on another Nuclepore® filter.

For the five filter samples in the first week and for two filter samples per week in the next weeks only the concentration of long fibers (L > 20 μm) was analyzed by counting of at least 100 long fibers.

This procedure is a modification of the EU protocol, which was also used in a calibration study for the EU at Fraunhofer ITEM (2001). Additionally, for one of these filter samples per group and week the fiber analysis was performed by counting and sizing including non-fibrous particles. The fiber concentration and the size distribution of fibers and particles were analyzed in SEM as described in the Section **3.4**.

5.3 Study Duration

The subchronic inhalation was performed from August 15 to November 14, 2002. The last sacrifice was on February 26, 2003.

5.4 Endpoints

The endpoints and the number of animals assigned for these investigations are listed in Table 2.

The study was subdivided into the following investigations:

1. Lung burden of test fibers in right lung lobes at end of exposure, 5 animals; in addition 10 animals were reserved for optional analysis at 2 different post-exposure sacrifice dates.
2. Bronchoalveolar lavage at 3 different sacrifice dates with a total of 15 animals per group.
3. Conventional lung histopathology and a cell proliferation measurement of the lung terminal bronchial airways, pleural cells and parenchymal cells by BrdU (S - phase response) using the left lung lobe of the same animals which were scheduled for lung burden analysis.
4. Gross necropsy findings and organ weights of all sacrificed animals.
5. Two animals were used as reserve animals in the event that animals died during the study.

For the cell proliferation measurement minipumps for administration of BrdU were implanted one day after end of exposure 4 days prior sacrifice. Therefore the first sacrifice date for histopathology and lung burden analysis was 5 days postexposure.

Table 2 List of investigations in the subchronic inhalation study
Exposure was terminated after 3 months; subgroups were kept for further 3 months for post-exposure investigations

Investigation	Test required after start of exposure [months]		Group	Number of animals per group for single investigation	Consecutive number of animals per group scheduled for investigation	
	Stage 1	Stage 2			Stage 1	Stage 2
Lung burden of test fibers	3	4.5; 6	1-4	5 [a]	1-5	6-10; 11-15
Bronchoalveolar lavage	3	4.5; 6	1-4	5	16-20	21-25; 26-30
Histopathology/ BrdU	3	4.5; 6	1-4	5	1-5	6-10; 11-15
Reserve animals			1-4	2	31,32	

[a] The left lung lobe of animals scheduled for fiber burden analysis was used for histopathology.

6 METHODS

6.1 Gross Pathology/Necropsy

All animals were subjected to a complete necropsy, which included careful examination of the external surface of the body, all orifices, and the cranial, thoracic and abdominal cavities and their contents. The rats were anaesthetized with an overdose of pentobarbital sodium (Narcoren™) and killed by cutting the vena cava caudalis. The abdominal cavity was opened and the diaphragm was cut carefully allowing the lungs to collapse. Heart, oesophagus, upper half of trachea, thymus and lung associated lymph-nodes (LALN) were removed from the lung convolution.

For lung burden analysis and histopathology the lung and the lower half of the trachea were weighed and after putting a tourniquet on the main bronchus to the right lung lobes these lung lobes were cut off at the lung tissue border and used for lung retention measurement. The right lung lobes were weighed and stored in plastic tubes (Greiner®) at -25±5°C. The left lung lobe was inflated under a pressure of 0.2 m H_2O with formalin and fixed by immersion for a minimum of 2 hours, and used for histopathology. Thereafter the weight of the lower part of the trachea was recorded and the weight of the left lung lobe was calculated as difference between total lung including lower part of trachea and the sum of right lung lobes and lower part of trachea.

6.2 Lung Burden Measurement

After sacrifice the right lung lobes were used for fiber retention analysis.

The lung tissue was dissolved by the same procedure which was used in previous studies after inhalation of toner (Muhle et al., 1990).

The lung tissue was placed in polypropylene centrifuge tubes, minced by scissors and digested in 4 ml of 25% tetramethylammonium hydroxide in methanol overnight at 50°C. Next the solution was cooled, diluted with 8 ml of methanol, sonicated for 10 min and then centrifuged for 25 at 39,000 x g. The liquid phase was removed and discarded, and the rinsing procedure was repeated. Next 4 ml freshly prepared 50% HNO_3 (made by mixing 65% HNO_3/Methanol; 10/4; v/v) was added, and the mixture was sonicated and incubated overnight at 50°C. After cooling, 8 ml methanol was added, and the mixture sonicated for 10 min and centrifuged. Again the liquid phase was removed and the rinsing procedure repeated. The remaining methanol was evaporated and the pellet was resuspended in water (containing 0.5% Tween® 80) and filtered on a Nuclepore® filter (25 or 47 mm diameter).

This procedure of lung digesting was validated prior to use. Three untreated lungs were spiked with 0.05, 0.1 or 0.5 mg of the test fibers. The mean fiber number (WHO and long fiber fraction) in the digested lung of each dose level was within 100% ± 25% and the size distribution of fibers recovered was not statistically different from the added test fibers (see Appendix 6). A report on the lung digestion validation was sent to the Study Monitor for approval prior to the digestion of any lungs from this study.

The fiber and particle concentration and the size distribution of fibers and particles were analyzed in SEM as described in Section **3.4**.

From the shape of the fibers and the density (1.0 g/cm^3 assumed for carbon fibers) the mass of the retained fibers was estimated assuming cylindrical geometry. From this data the total number of fibers per lung was calculated for each animal.

At the sacrifice date 15 weeks postexposure also the lung-associated lymph nodes (LALN) were prepared for fiber analysis (see study plan amendment 1 and 5). LALN of all animals per group of that sacrifice date were pooled, and treated and analyzed for translocated fibers using the same procedure as described for lungs.

6.3 Bronchoalveolar Lavage

At 4 days and 7 and 14 weeks post-treatment, a bronchoalveolar lavage (BAL) was performed and the lavage fluid collected for differential cell counts and analysis of biochemical parameters. With minor alterations, the procedure followed the method described by Henderson et al. (1987).

Following preparation, the lungs were lavaged with saline using five lavages of 5 ml each. The lavage fluid was collected separately for the lavages 1 and 2 (first series, without massage of lungs)

and for the lavages 3 to 5 (second series, using mild massage of lungs) in calibrated tubes and the collected volume was recorded. Until processing the lavage fluid was kept on ice.

After centrifugation of the combined lavage fluid of the lavages 1 and 2, biochemical indicators relevant for diagnosis of lung damage were determined in the supernatant (lactic dehydrogenase - LDH, β-glucuronidase, total protein).

The cell pellet of the first lavage series was resuspended in the residual supernatant, combined with the second lavage series and this suspension was used for cell analysis. Leukocyte concentration of the lavagate was determined using a counting chamber and two cytoslides were prepared with a cytocentrifuge (Shandon Co., Frankfurt, Germany) for differential cell count of leukocytes (macrophages, neutrophils, eosinophils, lymphocytes; additionally: epithelial cells). Another aliquot was used for a viability assay of lavaged cells (trypan blue exclusion test).

The justification of the parameters is given below:

Cytological parameters

- total cell count (recruitment of lung leukocytes)
- viability test (giving percentage of alive leukocytes among the total number of cells)
- differential cell count (inflammatory (PMNs) or immunological (lymphocytes) reactions)

Biochemical parameters

- lactic dehydrogenase (LDH = cytosolic marker enzyme; increased permeability of membranes, cell damage and lysis)
- β-glucuronidase (measure of phagolysosomal enzyme of macrophages; lysis of macrophages)
- total protein (marker of transsudation; damage of epithelial cells).

These parameters were analyzed according to routine clinical chemistry protocols using a Cobas Fara device (Roche Co., Grenzach, Germany):

Lactic Dehydrogenase (EC 1.1.1.27, U/l)

6.4 Histopathology

Conventional histopathological examination including fibrosis scoring (H&E staining and Masson-Trichrome staining) was performed on the left lung lobes and trachea (H&E staining only) of animals listed in **Table 2**. The McConnell-Wagner fibrosis scoring system (McConnell et al. 1984) was used. Additionally the EPS evaluation system including scoring for collagen deposition at the bronchiolo-alveolar junction (Annex in ECB/TM/16(97) rev, 1) was used. A quantitative evaluation of fibrosis using a morphometric method according to the criteria from J. Davis, IOM, Edinburgh was also done. The Wagner scoring system is from grade 1 to 8, and grade 4 correspond to evidence of early interstitial fibrosis. The EPS system includes grade 0 to 5 and grade 2 is corresponding to evidence of early interstitial fibrosis.

Formalin-fixed tissue of the terminal bronchioles, pleural cells and lung parenchymal cells were examined for cell proliferation using the sensitive S-phase response method. Proliferating cells were labeled by 5-bromo-2'-deoxyuridine (BrdU) which was administered to the animals by a minipump which was implanted prior to sacrifice. The lung section slides were prepared according to histological routine procedure and stained immunohistochemically following denaturation of the DNA (antibody technique). The slides were evaluated by analyzing an appropriate number of each airway cells and cells of the proximal regions of the pulmonary parenchyma per rat. In addition, pleural cells were analyzed and the unit length labeling index (ULLI) (at least 1 cm in length of pleura per lung section) estimated.

For the terminal bronchioles the Unit Length Labelling Index (ULLI) method was used. The ULLI of at least 4 terminal bronchioli (longitudinally sectioned) was determined. The number of BrdU-positive cells was recorded on a length of approximately 2 x 500 µm of bronchiolar epithelium, counting from the bronchiolo-alveolar transition towards the proximal terminal bronchiole and the number of BrdU-positive cells per mm of airway surface (or basement membrane) was calculated.

For the lung parenchyma four fields (top, below, right and left to the bronchiolus; distance of 1 alveolus between the counting frame and the bronchiolar wall, see **Fig. 2**) per evaluated bronchiolus were analyzed. All cells of the parenchyma were analyzed except cells of larger blood vessels, PMNs and intraalveolar macrophages which had no contact to the alveolar wall. A minimum of 2000 lung parenchymal cells were counted per animal.

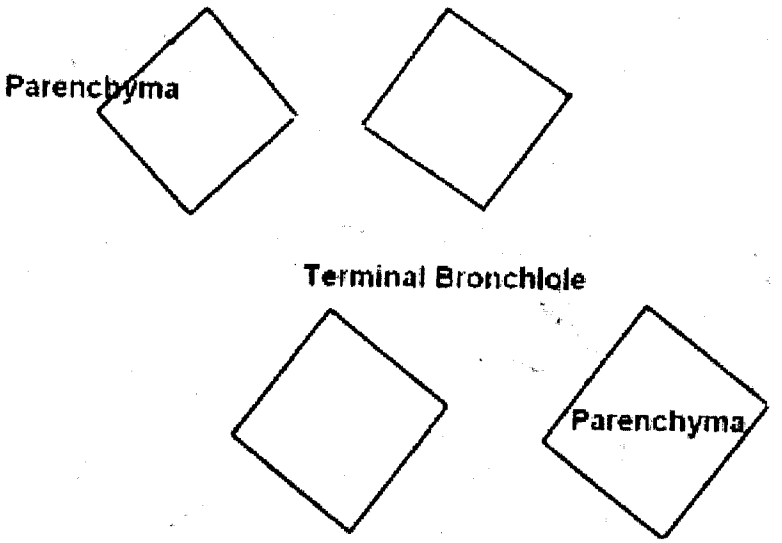

Fig. 2 Regions for analyzing of cell proliferation in lung parenchyma

6.5 Data Collection and Transformation

The data of fiber length and diameter were recorded on personal computers in the laboratory and were transferred to the central computer unit. The analysis of the data was done with the SAS software package (SAS Institute, Cary, NC, USA).

6.6 Evaluation of data

The individual toxicological data was compared to the clean air control group. For numeric parameters the statistics was done by using Dunnett's or Tukey's test. For comparison of histo-pathological findings a pairwise Fisher's exact test between control and treatment groups was performed.

6.7 Transfer of Electronic Data from Fraunhofer ITEM to the Sponsor

On request by the sponsor data which are stored electronically (body weight, lung wet weight, fiber length and diameter data) at Fraunhofer ITEM can be transferred to the sponsor.

Data may be transferred by email or by sending 3.5"-DS,HD Diskettes (1.44 MB) IBM formatted. The

format of the data will be specified by arrangement with the sponsor. After completion of the study the following data will be stored on a CD and sent to the sponsor (i.e. structure: study no., substance/group, animal no., exposure period, recovery period, parameters examined):

Study plan, final report, body weight (g), LDH (U/L), ß-Glucuronidase (U/L), total protein (mg/L), cell concentration (cells/ml), macrophages (%), PMN (%), lymphocytes (%), terminal body weight (g), lung wet weight (g), histopathological findings including semiquantitative assessment of fibrosis (EPS grade, Wagner grade), cell proliferation data (labelling index parenchyma, proliferation index terminal bronchioles, proliferation index pleural cells, fibers/lung, WHO fibers/lung, fibers (L>20μm)/lung, and particles/lung.

7 QUALITY ASSURANCE

The Quality Assurance Unit (QAU) of Fraunhofer ITEM inspected critical phases throughout the study and audited raw data and the reports.

8 STORAGE AND RETENTION OF RECORDS AND MATERIAL

After completion of the study and issuance of the final report, the study plan with amendments and deviations, the original final report, specimens of the test fiber, the samples for scanning electron microscopy, the raw data of all measurements and other material will be transferred to the archives of Fraunhofer ITEM. All materials will be properly indexed and catalogued and stored for the minimum period of time in compliance with GLP principles. The material to be retained is not limited to the list above. No materials will be disposed of without the written consent of the sponsor and Fraunhofer ITEM.

9 RESULTS

9.1 Concentration and Fiber Size Distribution in the Aerosol

The aerosol concentrations were measured by SEM.

The means and standard deviations of the fiber and particle concentrations in the aerosol samples of the three exposure chambers are summarized in **Table 3**. The data for individual days are shown in Appendix 4. The size distribution of the aerosol samples is presented in **Table 4** and **5**. The size distribution of individual days is shown in Appendix 5a.

9.2 Body Weights

The body weight development is presented in **Fig. 3**. Compared to controls all treatment groups showed a similar body weight increase during the study. The mean values and data of individual animals are listed in Appendix 1.

9.3 Lung Wet Weights and Terminal Body Weights

The lung wet weights were determined of lungs taken for retention and BAL measurements. These data are given together with the terminal body weights in **Table 6**. The individual animal data are listed in Appendix 2a.

The necropsy findings are summarized in Appendix 2b.

9.4 Retention of Fibers in the Lungs

The results of fiber retention are summarized in **Table 7**. At 15 weeks postexposure also the fiber content within the pooled lung associated lymph nodes (LALN) was analysed per group. The data for individual animals is listed in Appendix 7. From lung retention data the half-times for the clearance of fibres were calculated (see **Table 8**). The size distribution of fibers in lung and LALN for the different sacrifice dates is shown in **Table 9** for percentile values and in **Table 10** for arithmetic and geometric means. The size distribution of individual animals is shown in Appendix 5b.

9.5 Bronchoalveolar Lavage

During the recovery period bronchoalveolar lavages (BAL) were performed on 5 rats per group and sacrifice date (at the last sacrifice date 6 rats for the control group and 7 rats for treatment group were used). The following biochemical parameters were measured in the supernatant of the bronchoalveolar lavagate: lactic dehydrogenase (LDH), β-glucuronidase (βGL) and total protein.

The results are summarized in **Table 11** and in Appendix 3a.

The results of the differential cell count are presented in **Table 12**, Appendix 3b and **Fig. 4.**

9.6 Histopathology

9.6.1 Histopathological Findings

The results of the histopathological examination after 3 months of inhalation and 5 days postexposure period are summarized in **Table 13**. The results after a 8-week post-exposure period and a 15-week post-exposure period are also given in **Table 13**. Some light micrographs of the lungs of animals of the three treatment groups of the 15-week post-exposure sacrifice are presented in Appendix 9

The results of fibrosis evaluation are presented in **Table 14**

The individual animal data are shown in Appendix 8.

Results of the 5-days postexposure subgroup

Trachea:

Single males of the medium (no. 030003) and high (no. 040005) dose groups, respectively, showed a very slight (minimal) (multi)focal hyperplasia of mucous (goblet) cells within the epithelial lining of the trachea.

Lungs:

No relevant lesions (corresponding to Wagner grade 1 and EPS grade 0) were observed in the clean air control animals (group 01). The only finding in this group was a very slight focal alveolar histiocytosis in animal no. 010002.

All rats of the fiber inhalation groups (5/5, each group) had dose-dependent multifocal very slight (minimal) to moderate alveolar and interstitial accumulation of fiber-containing macrophages. A very slight degree of macrophage accumulation was observed in 5/5 animals of the low dose group (group 02) while all rats (5/5) of the medium dose group (group 03) showed slight accumulation of fiber-laden macrophages. The high dose group (group 04) had both slight (1/5) and moderate (4/5) degrees of fiber-associated macrophage accumulation. The fiber-laden macrophages were preferentially located in the alveolar duct region, either within alveoli or within the peribronchiolar/-interalveolar interstitium. In addition, 2/5 and all (5/5) males of the medium and high dose groups, respectively, showed very slight (group 03: 2/5; group 04: 1/5) to slight (group 04: 4/5) numbers of multinucleated giant cells (macrophages) which were associated with interstitial deposits of fibers.

Dose-dependent microgranulomas (foci of fiber-associated granulomatous inflammation) were seen in 5/5 rats of all fiber-exposed groups at very slight (group 02: 5/5), slight (group 03: 5/5; group 04: 3/5) to moderate (group 04: 2/5) degrees.

Another change which occurred dose-dependently at very slight (group 02: 4/5) to slight (group 02: 1/5; groups 03 and 04: 5/5 each) degrees in all animals of the fiber exposure groups was multifocal bronchiolo-alveolar hyperplasia, mainly of the bronchiolar type (alveolar bronchiolization). The

hyperplastic epithelium developed in association with inflammatory and fibrotic foci within the alveolar duct region and was usually continuous with the epithelium of the terminal bronchioles. In addition, 2/5 and 5/5 rats of the medium and high dose groups, respectively, revealed very slight (group 03: 1/5; group 04: 2/5) to slight (group 03: 1/5; group 04: 3/5) (multi)focal mucous (goblet) cell hyperplasia of the bronchiolar epithelium.

All rats of the fiber exposure groups showed dose-dependent very slight to slight multifocal interstitial fibrosis which mainly affected the bronchiolo-alveolar junctions. Interstitial fibrosis of slight degree (corresponding to Wagner-McConnell grade 4 and to EPS grade 2) was diagnosed in 2/5 and 5/5 rats of groups 03 and 04, respectively, while all (5/5) animals of group 02 and 3/5 rats of group 03 showed very slight (minimal) interstitial fibrosis (corresponding to Wagner-McConnell grades 3 and to EPS grade 1). Fibrosis of slight degree was also quantitatively evaluated according to the proposal of McConnell and Davis, the results are given in **Table 14**. EPS grade 2 and Wagner grade 4 correspond to evidence of early interstitial fibrosis.

Results of the 8-weeks postexposure subgroup

Trachea:

In none of the animals abnormalities were detected in the trachea.

Lungs:

No relevant lesions (corresponding to Wagner grade 1 and EPS grade 0) were observed in the clean air control animals (group 01).

All rats of the fiber inhalation groups (5/5, each group) had dose-dependent multifocal very slight (minimal) to moderate alveolar and interstitial accumulation of fiber-containing macrophages. A very slight (4/5 rats) to slight (1/5 rats) degree of macrophage accumulation was observed in the low dose group (group 02) while all rats (5/5) of the medium dose group (group 03) showed slight accumulation of fiber-laden macrophages. The high dose group (group 04) had both slight (2/5) and moderate (3/5) degrees of fiber-associated macrophage accumulation. The fiber-laden macrophages were preferentially located in the alveolar duct region, either within alveoli or within the peribronchiolar/interalveolar interstitium. In addition, 1/5 and 5/5 males of the low and medium dose groups, respectively, showed very slight and all (5/5) males of the high dose group slight numbers of multinucleated giant cells (macrophages) which were associated with interstitial deposits of fibers.

Dose-dependent microgranulomas (foci of fiber-associated granulomatous inflammation) were seen in 5/5 rats of all fiber-exposed groups at very slight (group 02: 4/5), slight (group 02: 1/5; group 03: 5/5; group 04: 3/5) to moderate (group 04: 2/5) degrees.

Another change which occurred dose-dependently at very slight (group 02: 3/5) to slight (group 02: 2/5; groups 03 and 04: 5/5 each) degrees in all animals of the fiber exposure groups was multifocal bronchiolo-alveolar hyperplasia, mainly of the bronchiolar type (alveolar bronchiolization). The

hyperplastic epithelium developed in association with inflammatory and fibrotic foci within the alveolar duct region and was usually continuous with the epithelium of the terminal bronchioles. In addition, 4/5 rats of the high dose groups, revealed very slight (group 04: 3/5) to slight (group 04: 1/5) (multi)focal mucous (goblet) cell hyperplasia of the bronchiolar epithelium.

All rats of the fiber exposure groups showed dose-dependent very slight to slight multifocal interstitial fibrosis which mainly affected the bronchiolo-alveolar junctions. Interstitial fibrosis of slight degree (corresponding to Wagner-McConnell grade 4 and to EPS grade 2) was diagnosed in 1/5 and 5/5 rats of groups 03 and 04, respectively, while all (5/5) animals of group 02 and 4/5 rats of group 03 showed very slight (minimal) interstitial fibrosis (corresponding to Wagner-McConnell grades 3 and to EPS grade 1). Fibrosis of slight degree was also quantitatively evaluated according to the proposal of McConnell and Davis, the results are given in **Table 14**. EPS grade 2 and Wagner grade 4 correspond to evidence of early interstitial fibrosis.

Results of the 15-weeks postexposure subgroup

Trachea:

A single male of the medium dose group (no. 030013) showed slight (multi)focal hyperplasia of mucous (goblet) cells within the epithelial lining of the trachea.

Lungs:

No relevant lesions (corresponding to Wagner grade 1 and EPS grade 0) were observed in the clean air control animals (group 01).

All rats of the fiber inhalation groups (5/5, each group) had dose-dependent multifocal very slight (minimal) to moderate alveolar and interstitial accumulation of fiber-containing macrophages. A very slight degree of macrophage accumulation was observed in 5/5 animals of the low dose group (group 02) while all rats (5/5) of the medium dose group (group 03) showed slight accumulation of fiber-laden macrophages. The high dose group (group 04) had both slight (1/5) and moderate (4/5) degrees of fiber-associated macrophage accumulation. The fiber-laden macrophages were preferentially located in the alveolar duct region, either within alveoli or within the peribronchiolar/-interalveolar interstitium. In addition, 1/5 and 3/5 males of the low and medium dose groups, respectively, showed very slight and 2/5 and all (5/5) males of the medium and high dose groups, respectively, slight numbers of multinucleated giant cells (macrophages) which were associated with interstitial deposits of fibers. Dose-dependent microgranulomas (foci of fiber-associated granulomatous inflammation) were seen in 5/5 rats of all fiber-exposed groups at very slight (group 02: 5/5), slight (group 03: 5/5; group 04: 3/5) to moderate (group 04: 2/5) degrees.

Another change which occurred dose-dependently at very slight (group 02: 3/5; group 03: 1/5) to slight (group 02: 1/5; group 03: 4/5; group 04: 5/5) degrees in all animals of the fiber exposure groups (except one rat of the low dose group) was multifocal bronchiolo-alveolar hyperplasia, mainly

of the bronchiolar type (alveolar bronchiolization). The hyperplastic epithelium developed in association with inflammatory and fibrotic foci within the alveolar duct region and was usually continuous with the epithelium of the terminal bronchioles. In addition, 2/5 rats of the medium and high dose groups each revealed very slight (group 03: 1/5; group 04: 2/5) to slight (group 03: 1/5) (multi)focal mucous (goblet) cell hyperplasia of the bronchiolar epithelium.

All rats of the fiber exposure groups (except two rats of the low dose group) showed dose-dependent very slight to slight multifocal interstitial fibrosis which mainly affected the bronchiolo-alveolar junctions. Interstitial fibrosis of slight degree (corresponding to Wagner-McConnell grade 4 and to EPS grade 2) was diagnosed in 1/5 and 5/5 rats of groups 03 and 04, respectively, while 3/5 animals of group 02 and 4/5 rats of group 03 showed very slight (minimal) interstitial fibrosis (corresponding to Wagner-McConnell grades 3 and to EPS grade 1). In addition, 2/5 rats of the low dose group without multifocal interstitial fibrosis had Wagner-McConnell grades 3 and EPS grade 1. Fibrosis of slight degree was also quantitatively evaluated according to the proposal of McConnell and Davis, the results are given in **Table 14**. EPS grade 2 and Wagner grade 4 correspond to evidence of early interstitial fibrosis.

10 STUDY PLAN ALTERATIONS

In one study plan amendment it was documented that for some filter samples with low content of fibers with length < 5 μm less than 100 fibers of that category were analyzed. Another amendment describes that the clinical chemistry was taken over by Dr. Hansen at the end of 2002. Additionally, in one amendment it was decided to change the last sacrifice date to February 26, 2003, to use the reserve animals (no. 32 of group 1, no. 31 and 32 of groups 2 to 4) for BAL at the last sacrifice date and to weigh and preserve the LALN at the last sacrifice date for optional fiber retention analysis.

In the 4th amendment it is documented that the exact sacrifice dates were 7.57 (BAL) and 7.71 weeks (Retention/Patho) which is rounded to 8 weeks instead of 7 in the study plan. For the last sacrifice date the exact dates were 14.71 (Retention/Patho) and 14.86 weeks (BAL) which has to be rounded to 15 weeks instead of 14 weeks in the study plan. Additionally a spelling mistake was corrected, the Tween concentration for resuspending of carbon fibers in lung tissue samples was 0.05 % instead of 0.5% in the study plan.

In the 5th amendment it is documented that the optional fiber analysis in the lungs for sacrifice dates 8 and 15 weeks postexposure and in the LALN at 15 weeks postexposure were performed on request of the sponsor.

In a deviation to the study plan it was documented that an additional signed report was drawn up for stage 1 of the study (containing results of exposure period and the first sacrifice date 1 week postexposure).

11 DISCUSSION

General

The aim of the study was to investigate the intrinsic toxicity of carbon fibers with a mean diameter of about 1 μm in rats after subchronic inhalation according to the protocol ECB/TM 16 (97) rev. 1.

The objectives of this study were:

- to investigate the effects of fibers on their inflammatory potential, the proliferation of alveolar epithelium, and the persistence of these effects during a recovery period of 3 months.

Rats were exposed 6 hours per day, 5 days per week for 3 months. The target dose was an exposure to 15, 50 and 150 fibers/ml at a fiber length > 20 µm. As **Table 3** shows these concentrations were reached.

The mean gravimetric concentrations in the exposure chambers were 2.1, 6.7 and 20.6 mg/m^3 for the three dose groups. The diameter of the fibers in the aerosol (see **Table 5**) was close to the value of 1.0 µm which is corresponding to the preferred 0.8 μm (fibers with density of 2.4) for the long fiber fraction (length > 20 µm) in the EC Guideline ECB/TM 16 Rev. 1. The mean geometric diameter of fibers with length > 20 µm were 1.14, 1.19, and 1.20 µm for low, medium and high dose, respectively. The corresponding values for the WHO fibers were 1.00, 1.04, and 1.03 μm.

After exposure of rats to the test fibers no biological effects were observed except that in the lungs.

Biological effects measured included the inflammatory and proliferative potential and histopathology lesions.

Body Weights

Body weight development during the exposure and posttreatment period did not show any evident differences between fiber treatment groups and the control group.

Wet Weights of Lungs

In the medium and high dose groups a statistically significant increase of the lung weight was observed up to 3 months postexposure (see **Table 6**). In the low dose group a significant increase was seen only at the first sacrifice date 1 week postexposure.

Retention of Test Fibers in the Lungs

After 3 months of exposure the lung retention of WHO fibers in fibers per lung was about 13 x 10^6, 62 x 10^6 and 145 x 10^6 for low, medium, and high dose, respectively (see **Table 7**). The corresponding values for long fibers (length > 20 µm) were about 3.3 x 10^6, 10.8 x 10^6 and 31.5 x 10^6 for the three groups. The corresponding values for the retained mass of fibers (estimation from the number and size of fibers in the lung ash) in the lungs in mg/lung were 0.27, 1.0, and 2.8 for low,

medium, and high dose, respectively. The estimated particle mass was less than 20% of the corresponding fiber mass in the lungs for all fiber groups.

After 3 months of recovery the WHO fiber concentration in the lungs decreased to 55%, 50% and 67% for the low, medium and high dose group, respectively. For the long fiber fraction with length > 20μm the corresponding data were 77%, 89% and 93% for the three dose groups. The elimination of fibers is slower in the high dose group compared to the low and medium dose group. Additionally the elimination of the long fiber fraction is much slower than for the WHO fiber fraction, which is different to the clearance behavior of man-made vitreous fibers. For most MMVFs a faster clearance was detected for the long fiber fraction compared to the WHO fiber fraction.

BAL

The effects on biochemical parameters (LDH and protein) in the BAL fluid were statistically significant at the end of the 3 months exposure and at 8 and 15 weeks postexposure for the high dose groups (**Table 11**). For the medium dose group the effect on protein was statistically significant and the effect on LDH was not significant for all sacrifice dates. For the low dose group only the protein was increased significantly only at end of exposure. The effect on ß-glucuronidase was significant only for the high dose group at end of 3 months exposure but not for later sacrifice dates. For the low and medium dose group the small increase of ß-glucuronidase was not significant for all sacrifice dates.

For medium and high dose fiber groups a statistically significant increase of neutrophil PMN and a reduction of the percentage of macrophages in the BALF was observed for all sacrifice dates, but the effect was less for 8 weeks and 15 weeks postexposure (**Table 12**). There was also a significant increase in lymphocytes in the mid and high dose groups up to 3 months postexposure. No significant effect was seen in the low dose group.

Histopathology

At the termination of the 3-month exposure period, very slight to moderate morphological changes were diagnosed (**Table 15**). These changes included alveolar macrophage aggregation and/or microgranulomas at the bronchiolo-alveolar junction in the few rats affected. At the end of exposure evidence of early interstitial fibrosis was detected for 2 rats of the medium dose group and for all 5 rats of the high dose group (**Table 15**). At 8 and 15 weeks postexposure this effect decreased to one rat of the medium dose group, but was retained at 5 rats for the high dose group

The cell proliferation was enhanced at end of exposure in the high dose group for the bronchiolar epithelium, for alveolar parenchymal cells and for pleural cells, in the medium group for the bronchiolar epithelium and for alveolar parenchymal cells, and in the low dose goup only for the bronchiolar epithelium (**Table 16**).

For the alveolar parenchymal cells the increase of cell proliferation persisted significantly for the high

dose group up to 3 months, but for the medium dose group it was no longer significant at 3 months postexposure. For the cell proliferation of the bronchiolar epithelium the increase retained significant up to 3 months postexposure for all treatment groups. This effect corresponds to the histopathological finding of bronchio-alveolar hyperplasia, which is a cellular response to fiber deposition and retention at the bronchioalveolar epithelium. This is an protective effect to increase the mucus production for enhancement of clearance of fibers in that region.

Overall assessment

In a previous study at Fraunhofer ITEM (Bellmann et al, 2003) three other fiber types (E-glass microfibers, stonewool MMVF21 and the biosoluble Calcium-Magnesium-Silicate [CMS] fiber) were investigated in a 90 day inhalation study using the same protocol (ECB/TM 16(97) rev. 1).

The effects for different parameters are plotted versus the retained number of long fibers (length>20μm) in Figures in Appendix 10.

The results of comparison the effects of carbon fibers to that of E-glass, MMVF21 and CMS are summarized in **Table 17.**

For the cell proliferation results a statistical analysis was done by comparison of carbon fiber induced effects to the dose groups of E-glass microfiber, MMVF21 and CMS fiber with comparable lung burden of test fibers (see App. 11). Only for the cell proliferation of the bronchiolar epithelium the increase induced by carbon fibers was significantly higher at 8 and 15 weeks postexposure comparing medium dose carbon fibers to E-glass medium dose and at 15 weeks postexposure when comparing low dose carbon fibers to MMVF21 medium dose.

Table 17 Effects of Carbonfibers in comparison to E-glass, MMVF21 and CMS (for the same lung retention of long fibers)

1 CONFIDENTIALITY STATEMENT

This report contains unpublished results and may not be cited or reproduced by any means in whole or in part without the permission of [redacted]

2 STATEMENT OF COMPLIANCE

RCC Study Number	801314
Test Item	CARBON FIBRE
Study Director	Paul A. Smith
Title	CARBON FIBRE: 3-Month Biopersistence Inhalation Study in the Rat

This study was performed in compliance with the Swiss Ordinance relating to Good Laboratory Practice, adopted February 2nd, 2000 [RS 813.016.5]. This Ordinance is based on the OECD Principles of Good Laboratory Practice, as revised in 1997 and adopted November 26th, 1997 by decision of the OECD Council [C(97)186/Final].

The present statement applies to the work performed at RCC Ltd, Wölferstrasse 4, CH-4414 Füllinsdorf & Zelgliweg 1, CH-4452 Itingen. Technical trials performed prior to the start of the study are not covered by GLP Regulations.

The GLP compliant performance of the preparation of lung samples was the responsibility of RCC Ltd, Environmental Chemistry & Pharmanalytics Division.

GSA is responsible for the part of the study performed at it's facility.

The composition or purity of the test item was not stated, this information is excluded from the statement of compliance.

There were no circumstances that may have affected the quality or integrity of the study.

Study Director Paul A. Smith

STATEMENT

RCC Study Number	801314
Test Item	CARBON FIBRE
Study Director	Paul A. Smith
Title	CARBON FIBRE: 3-Month Biopersistence Inhalation in the Rat

The general facilities and activities are inspected periodically and the results are reported to the responsible person and the management.

Study procedures with the exception of the pre-tests were periodically inspected. The study plan and this report were audited by the Quality Assurance Unit. The dates are given below:

Dates and type of QAU Inspections / Audits		Dates of Reports to the Study Director and to Management
02-AUG-2001	Study plan	02-AUG-2001
15-AUG-2001	Study based (test system, test item, treatment, observations, raw data)	15-AUG-2001
17-AUG-2001	Study based (test item, raw data)	17-AUG-2001
22-AUG-2001	Study based (necropsy, raw data)	22-AUG-2001
08-OCT-2001	Study based (test system, observations, raw data)	08-OCT-2001
19-NOV-2001	Study based (necropsy)	19-NOV-2001
27 to 29-AUG-2002	Report	29-AUG-2002

This statement also confirms that this final report reflects the raw data.

4.4 ARCHIVING

RCC Ltd (CH-4452 Itingen, Switzerland) will retain the study plan, raw data, a sample of test item(s), specimens and the final report of the present study for at least ten years. No data will be discarded without the Sponsor's consent.

Excluded are the study material and samples forwarded by RCC to GSA, who will archive the material under their responsibility.

4.5 METHOD GUIDELINES

The study procedures in this study were based on the EU Guidelines: Biopersistence of Fibres. Short Term Exposure by Inhalation, ECB/TM/26 rev. 7, 1998.

4.6 SUMMARY OF DEVIATIONS

The identification of the 14-day and the 30-day sacrifices were corrected and adapted to 15-day and 29-day sacrifices, respectively.

The description of the generation system was adapted.

Clinical signs and body weights were recorded more often than stated in the study plan.

In the first amendment to study plan, no management signature was included. Management documented their approval of the contents later, on a separate document.

The purity of the test item was not added by amendment.

The method for chemical digestion of the freeze-dried lungs was not specified by amendment to study plan.

No statistical analysis of the non-fibre particles was performed.

5 SUMMARY

The purpose of this study was to assess the in-vivo pulmonary biopersistence of inhaled fibrous and non-fibrous particles in the rat following repeated inhalation exposure.

Laboratory rats were randomly assigned to one negative control group and to one group exposed to the test item, Carbon Fibre. The animals were exposed to filtered air (negative control) or to well characterised fibres which were sized to be rat respirable using a flow past, nose only exposure system. In the fibre-exposed group, the concentration was targeted to 15 mg/m^3 if technically feasible. The achieved concentration was 16 mg/m^3. The rats were exposed for five consecutive days, 6 hours per day, with a subsequent non-exposure period. In the control and in the fibre-exposed groups, rats were allocated to sub-groups of 5 and 7 animals respectively and sacrificed at 1 day, 3 days, 15 days, 29 days and 92 days.

For each of the sacrifice time-points the lung burden was determined by suitable extraction and measurement methods. Evaluation included counting of the number of fibres and particles in the lungs and characterisation of the fibres by bivariate analysis of diameter and length.

5.1 ANIMAL DATA

The in-life data recorded during the study - mortality, clinical signs and body weights - gave no indications of fibre-related findings.

Macroscopic findings at the 1 and 3-day sacrifice time-points indicated a minor, acute response to inhalation of a particulate material. Increased lung weights at the 29 and 92-day sacrifice time-points were observed, but it is not clear as to whether these were treatment related.

5.2 LUNG BURDEN DATA

The main results of lung burden analyses by SEM performed at GSA are summarised below. Details are presented in Attachment 2.

Group 2, CARBON FIBRE						
time point	1 day	3 days	15 days	29 days	92 days	T ½ days
FIBRE NUMBER (10^6 / lung)						
Total fibres/lung	83.858	82.122	61.764	53.500	25.378	45.13s
WHO fibres/lung	51.676	48.074	37.825	33.259	15.705	50.36s
Fibres/lung < 5 µm	30.676	32.583	22.716	18.932	9.195	47.14d
Fibres/lung 5-20 µm	50.133	46.599	36.716	32.377	14.450	46.10s
Fibres/lung > 20 µm	3.049	2.940	2.332	2.191	1.734**	99.86s
Total length of fibres/lung (m)	637.3	603.1	473.3	417.4	213.5	49.82s
Non-fibre particles	42.148	55.080	40.861	36.714	17.961	---
n=	6*	7	7	7	7	

* Animal 22 was excluded because the value of the total fibre length (m), and the total number of fibres per lung, differed from the average value of all animals evaluated at the same time-point by more that two times the value of the standard deviation.

** The number of fibres > 20μm was statistically significantly lower ($p < 0.01$) on day 92 compared with day 1.

s Single exponential

d double exponential (weighted value)

6 PURPOSE

The purpose of this study was to assess the in-vivo pulmonary biopersistence of inhaled fibrous and non-fibrous particles in the rat following repeated inhalation exposure for 5 days.

Laboratory rats were randomly assigned to one negative control group and to one group exposed to the test item, Carbon Fibre. The animals were exposed to filtered air (negative control) or to well characterised fibres which were sized to be rat respirable using a flow past, nose only exposure system. In the fibre-exposed group, the concentration was targeted to 15 mg/m^3. The rats were exposed for five consecutive days, 6 hours per day, with a subsequent non-exposure period. In the control and in the fibre-exposed groups, rats were allocated to sub-groups of 5 and 7 animals respectively, planned for sacrifice at 1 day, 3 days, 15 days, 29 days and 92 days.

The lung burden was determined at the different sacrifice time-points by suitable extraction and measurement methods. Evaluation included counting of the number of fibres and particles in the lungs and characterisation of the fibres by bivariate analysis of diameter and length.

7 MATERIALS AND METHODS

7.1 TEST SYSTEM

Test System	Male Wistar Rat, HanBrl:WIST (SPF)
Rationale for Selection	Routinely used as a standard for studies with natural and/or man-made fibres
Source	RCC Ltd, Biotechnology and Animal Breeding Division (RCC BAB) Wölferstrasse 4, CH-4414 Füllinsdorf, Switzerland
Number of Groups	2
Number of Animals per Group	Air control: 15 rats Treated group: 35 rats
Total Number of Animals in the study	55 (including 5 reserve animals)
Body Weight at Delivery	183.8 - 208.8 grams
Age at Delivery	9 weeks
Acclimatisation	From 03 to 14-AUG-2001. A clinical health examination was performed on all animals shortly after delivery. There were no visible findings of illness and all animals entered the acclimatisation phase. No substitution of study animals with reserve animals was necessary prior to the start of the exposure and all reserve animals were sacrificed on the first day of treatment, before treatment start.
Randomisation	On the day of delivery (03-AUG-2001), all animals were assigned to the different groups using a random sampling procedure stratified by body weight.
Identification	By ear tattoo. Housing cages were identified with the appropriate animal numbers. During the first seven days of the acclimatisation phase, the animals were identified by cage numbers and code on the tail.

Habituation to restraint The rats were accustomed to the restraint tubes during the acclimatisation phase by maintaining them in tubes for 5 daily periods of approximately 30 minutes, 1, 2, 4 and 5 hours.

7.2 ALLOCATION

Sacrifice Time Points	Group 1, Air Control	Group 2, Carbon Fibre
1 Day	1 – 5	16 - 22
3 Days		23 - 29
15 Days		30 - 36
29 Days	6 – 10	37 - 43
92 Days	11 – 15	44 - 50
Reserve animals	51 - 55	

7.3 HUSBANDRY

Room Numbers

Acclimatisation, treatment, first 6 days of recovery Room 3.16 (RCC, Füllinsdorf)
From day 7 of recovery until the end of the study Room 3.06 (RCC, Füllinsdorf)

Laboratory Conditions

The study was conducted under Optimal Hygienic Conditions (OHC) behind a barrier system. The conditioned air was supplied with 10-15 air changes per hour, a monitored environment with target range for temperature of 22 ± 3°C and for relative humidity of 30 - 70%, a period of 12 hours of artificial fluorescent light and a 12 hour dark period. Music was played during the major part of the light period.

Accommodation

Animals were housed in groups of 5, maximally, in Makrolon® Type IV cages with wire mesh tops and standard, dust-free softwood bedding ("Lignocel", Schill AG, CH-4132 Muttenz, Switzerland) during the major part of the acclimatisation and post-exposure phases. From day 8 of acclimatisation until day 3 of recovery, the animals were housed in sealed, negative pressure chambers used for group isolation. Bedding and cages were autoclaved before use. Tubes and plastic equipment were exposed to formaldehyde vapour before use.

Diet

Pelleted standard Kliba 3433 rat maintenance diet, batches no. 71/01 and 73/01 (Provimi Kliba AG, CH-4303 Kaiseraugst) *ad libitum*. Results of analysis for contaminants with acceptability limits are included in this report (Attachment 1, pp. 70 to 73).

Water

Community tap water from Füllinsdorf, chlorinated to approximately 0.5 ppm, *ad libitum*. Results of bacteriological, chemical and contaminant analysis with acceptability limits are included in this report (Attachment 1, pp. 74 to 76).

None of the contaminants present in the water and diet were expected to interfere with the study.

7.4 TEST ITEM

Identification / Test Item Name	CARBON FIBRE
Batch Number	P133-250401
Purity	Not stated
Expiry Date / Stability	December 2003
Instructions for Storage	In the original container at room temperature (19-25°C) protected from sunlight and moisture
Safety precautions	During the whole study, the use of a full face positive filtered (S3) air supply respirator, gloves and complete change of laboratory clothing was required.

Preparation of the Stock Fibres

The material produced by the Sponsor and submitted to RCC was referred to as *bulk material*. The material used for aerosolisation was referred to as *stock fibre* and was obtained from the bulk material.

The stock material was prepared at RCC and characterised at GSA. The dimensions of the stock material are summarised below:

	CARBON FIBRE	
	Diameter	**Length**
Geometric Mean (µm)	0.93	7.27
Geometric Mean F> 20 µm (µm)	1.54	27.25
% of fibres with L>20 µm	9.1	

7.5 TREATMENT

Route of administration	Inhalation by nose only exposure. This method of administration closely mimics that in humans and represents the natural route of uptake
Frequency and duration	6 hours/day, during 5 consecutive days

Target Exposure Concentrations

The exposure level was adjusted in accordance with the following criteria:

	Test Item	**Exposure Concentration**
Group 1	Filtered air	---
Group 2	Carbon Fibre	15 mg/m^3

The target exposure level was selected based upon the technical trials and in agreement with the Sponsor and the Monitoring Scientist.

The air control animals (Group 1) were treated with filtered air under the same conditions as animals exposed to fibres.

7.6 INHALATION EXPOSURE SYSTEM

Inhalation exposure was performed using a system similar to that originally described by Sachsse et al[1]. (1973, 1976). The animals are confined separately in Makrolon® tubes which are positioned radially around a flow-past, nose-only exposure chamber[2]. The design of this exposure system is based upon fluid dynamic modelling of the aerosol flow and is unique in comparison with conventional nose-only exposure systems in that it ensures a uniform test item distribution, provides constant stream of "fresh" test item to each animal, and precludes rebreathing from the exhaled air. The aerosol stream reaches the animal's nose through ports situated at different levels around the axis of the exposure chamber. Each level can be rotated allowing close observation of all animals without interruption of exposure.

7.6.1 GENERATION OF TEST AND REFERENCE TEST ITEMS

A fibre aerosol was produced using the RCC Fibre Aerosol Generation System. After passing through a cyclon (diameter, 5 cm) the fibre aerosol was delivered directly into the flow-past exposure chamber.

7.6.2 EXPOSURE SYSTEM MONITORING

Airflow Rate

Monitored daily by constant air pressure for the generation and by flow meter at the chamber extraction.

Oxygen Concentration

Monitored continuously during each exposure, at the position of the animal's snout, using an oxygen sensor (Pewatron AG, CH-8304 Wallisellen, Switzerland), connected to a datalogger.

Temperature and Relative Humidity

Monitored continuously in the air supply for the fibre generator, just prior to the fibre aerosol generation system, using a Rotronic Hygrometer, Serie I-200 (Rotronic AG, CH-8040 Zürich, Switzerland), connected to a datalogger. Although there were no specific targets set the purpose of monitoring these parameters was to avoid water condensation forming in the fibre generator, which could have occurred at high humidity and low temperatures.

7.6.3 TEST ATMOSPHERE MONITORING

Technical Trials

Preliminary generation trials were performed at different gravimetric concentrations. The collected filters were forwarded to GSA for counting and sizing. On the basis of these results and in agreement with the Sponsor a gravimetric concentration of 15 mg/m^3 was chosen for exposure of the animals.

General

All fibre samples were collected on the appropriate filters in the vicinity of the animal's snout. On the inhalation tower the level of the port selected for inserting the filter holders was changed daily by one level occupied by the animals. Each day, filter holders for aerosol mass monitoring and for filter collection for other investigations was positioned at the same level.

One day during the exposure phase, simultaneous gravimetric samples were taken at all levels, for documenting that the uniformity for fibre concentrations at all levels was within ±15% of the average value.

Aerosol Mass Monitoring

In both groups, samples were collected daily on MILLIPORE membrane filters (Durapore HVLP, diameter 47 mm, pore size 0.45 μm). The duration of sampling was at least 5 hours. One sample was collected each day except on the second day when three samples, one at each level, were collected for the carbon fibre exposure chamber.

All collected samples were weighed for aerosol mass monitoring, and the results are presented in the report. All filters were discarded following the end of the exposure phase.

Short gravimetric samples were taken for daily fine adjustment of the concentrations. No specimens and no records were maintained. Additionally a Real Time Aerosol Sensor (RAS-2, MIE Inc., Bedford, MA 01730, USA) was used for technical monitoring during exposure time. This system allowed for the real time assessment of the exposure concentration. When calibrated and monitored, changes or malfunctions associated with the exposure system could be identified and corrected. Since this device was used for technical monitoring only, no data were reported, although some may be stored or may appear in the raw data.

Filter Collection for Other Investigations

In both groups, samples were collected daily on NUCLEPORE® filters (PC membrane, diameter 47 mm, pore size 0.2 μm). The duration of sampling was at least 5 hours and simultaneous with the gravimetric samples.

Two parallel samples were taken each day. One of them, scheduled for investigations, was sent to GSA. The other one was retained dry at RCC at disposal of the Sponsor, until issuing of the final report. Upon consultation with the Sponsor and unless otherwise requested, the retained samples were then discarded.

7.7 IN-LIFE OBSERVATIONS

Mortality

All animals were observed for mortality/moribundity once daily during the acclimatisation and recovery periods, and twice daily, once before and once after exposure, during the five days of the treatment phase.

Clinical Signs

Each animal had a detailed clinical observation for toxicological signs, including time of onset, intensity and duration:

- once on day 1 and once on day 8 of the acclimatisation phase
- twice daily (once before and once after the daily application) during the 5 treatment days
- once on the first day of recovery and at least once weekly thereafter.

Body Weights

Body weights were recorded:

- once on day 1 (used for randomisation) and once on day 8 of the acclimatisation phase
- on the day of first administration, prior to the administration start
- once on the first day of recovery and at least once weekly thereafter.

7.8 PATHOLOGY

Necropsy

All animals were necropsied for lung burden analysis according to the following schedule:

Sacrifice Time Points	Date	Group 1 Air Control	Group 2 Carbon Fibre
1 Day (24 ± 2 hrs)	20-AUG-2001	1 - 5	16 - 22
3 Days (72 ± 2 hrs)	22-AUG-2001	---	23 - 29
15 Days	03-SEP-2001	---	30 - 36
29 Days	17-SEP-2001	6 - 10	37 - 43
92 Days	19-NOV-2001	11 - 15	44 - 50

All animals were anaesthetised with an intraperitoneal injection of sodium pentobarbital (approximately 300 mg/kg bw.) and sacrificed by exsanguination.

The rats were submitted to complete macroscopical observation, including careful examination of the external surface of the body, thoracic and abdominal cavities and their contents. Gross findings at necropsy were recorded.

Organ Sampling

All action was taken to avoid contamination of the dissected specimen by fibres from the fur or deposited on dissecting instruments. Special care was taken to avoid inter-group contamination. During each necropsy session, air control animals were dissected first.

For each animal the following procedure was followed:

- **The lungs and trachea** (sectioned below the larynx) were removed with the attached mediastinal tissue. The mediastinal tissue containing the mediastinal lymph nodes was resected and immediately deep-frozen on dry ice and then stored at -20°C or below, at RCC for possible investigations prescribed by the Sponsor under separate contractual agreement. However, if not used, storage of these specimens ends by the time of submission of the final report. The remaining tissue/organs: lower half of the trachea, main stem bronchi and lungs were weighed (recorded as "lung weight").
- **The trachea and the main stem bronchi** down to the limit of the lung lobes were resected in one piece, weighed (recorded as "trachea"), individually inserted into plastic bags appropriately labelled and immediately deep-frozen on dry ice and then stored at -20°C or below, at RCC for possible investigations prescribed by the Sponsor under separate contractual agreement. However, if not used, storage of these specimens ends by the time of submission of the final report.
- **All lung lobes** were weighed together (recorded as "all lung lobes"), immediately deep-frozen on dry ice and forwarded (deep-frozen) to RCC ECP (attn: M. Kern). The lungs were freeze dried, weighed (recorded as "dry lung weight"), inserted into a plastic bag appropriately labelled, then stored in a desiccator at room temperature until further processing.

All freeze-dried lungs were chemically digested according to a method established at RCC and sent to GSA for lung burden investigations. The method comprised digesting the lungs in a heated acid mixture for a set duration followed by similar treatment with an oxidising agent and then vacuum filtering to trap the organic fibres on polycarbonate filters.

8 INVESTIGATIONS AT GSA

All specimens were sent from RCC TOX to GSA.

A signed and dated chain of custody form accompanied all samples sent to GSA. The chain of custody forms are archived at the GSA facilities. From the time of delivery at GSA, the specimens were under their responsibility. Preparation procedures as well as GLP regulation compliance are specified in the report submitted by GSA (Attachment 2).

The fibre-loaded Nuclepore filters scheduled for investigation by GSA were placed individually into 100 ml glass flasks with the appropriate care to preclude any spillage. The flasks containing the dry filters were sealed with a plastic top, adequately labelled and express mailed under ambient conditions to GSA. Each sample was labelled with the RCC study number, RCC filter number, group number and date of sampling.

The containers with the digested lung samples were express mailed under ambient conditions to GSA. Each sample was labelled with the RCC study number, animal number, group number and fibre identification, date of necropsy and name of tissue.

An overview of the number of samples investigated at GSA is presented below:

Group	Exposure Aerosol	
	F/ml	BVA
1 Air Control	5	---
2 Carbon Fibre	5	5

Group	Lung Burden: F/Lung and BVA				
	1 day	3 days	15 days	29 days	92 days
1 Air Control	5	---	---	5	5
2 Carbon Fibre	7	7	7	7	7

BVA = Bivariate analysis of fibre size distribution
F/ml = Fibre counting (expressed in fibre number per ml of suspension)
F/lung = Fibre per lung

9 STATISTICAL ANALYSIS

Analysis of weights

The following statistical methods were used to analyse body weight and organ weights:

- If the variables could be assumed to follow a normal distribution, the t-test comparing both groups was used.
- The Steel-test (many-to-one rank test) was applied when the data could not be assumed to follow a normal distribution.

Group means with standard deviations (S.D) were calculated for continuous data; for discrete data (scores), medians were calculated.

Analysis of lung burden data

The list of parameters is available in the report by GSA filed in Attachment 2 of the present report.

Analysis of Fibre Biopersistence in Lungs

The biopersistence of fibres in the rat lung was expressed by the half-time value ($T_{1/2}$), derived from the mathematical description of the fibre clearance:

The clearance was calculated for the following categories:

- total fibres
- WHO-fibres
- total fibres < 5 µm
- total fibres ≤ 5 µm and < 20 µm
- total fibres ≤ 20 µm

The clearance was essentially calculated by using the procedure described in the European regulations ECB/TM/27 rev. 7, Sections 2.5.2 and 2.5.3:

- the 100% value was fixed at day one after cessation of exposure
- a non-linear, single exponential regression was used to fit the data if the regression explained at least 80% of the variance: percent fibre remaining =
- otherwise a two-exponential was used:
- percent fibres remaining = a1*exp(-b1*days)+a2*exp(-b2*days)

The clearance half-time was calculated as follows:

- case of a single exponential: T1/2 = ln2/b
- case of a double exponential: summing the product of each half-time value by its coefficient ax.

All animals were used for evaluation, except if the value of the total fibre length (m), and the total number of fibres per lung, differed from the average value of all animals evaluated at the same time-point by more than two times the value of the standard deviation. In this case, the animal was removed from the statistical evaluation.

A SAS/STAT statistical analysis was also performed on the number of fibres longer than 20 µm at all time-points using the day 1 value as reference.

10 DATA COMPILATION

Body weights, organ weights, mortality, clinical signs and macroscopical findings at necropsy were recorded on-line or on data sheets and then transferred into the Digital VAX computer system for compilation.

The fibre aerosol monitoring data were recorded on data sheets and manually entered into Microsoft Excel97 tables for calculations.

Individual values were rounded before printing. All derived values that appear in the tables represent the rounded results of calculations, which used the exact raw data value.

11 RESULTS

11.1 EXPOSURE CONDITIONS

During the daily 6-hour exposure period, rats were maintained in restraint tubes placed radially on inhalation towers, installed in Hazleton 2000-type chambers for group isolation. The humidity in the generator air was kept between 1.8 and 1.9% to avoid condensation of water in the fibre generator, and the temperature of the generator air remained between 21.2 and 21.9°C.

The airflow for group 1 remained at 32 litres/minute and the air pressure for group 2 at 0.3 bar, equating to 81 litres/minute. Each system comprised of 7 stages with 16 outlets/stage. For each group the appropriate number of outlets remained open to provide airflow of 1 litre/minute at each outlet. The oxygen concentration in the exposure system for groups 1 and 2 was between 20.8 and 21.8%.

The temperature and relative humidity in the animal room were recorded manually 3 times per exposure and remained stable between 21.4 and 22.0°C and 63.4 and 73.7% respectively.

11.2 AEROSOL DATA

Aerosol Concentrations

	Aerosol Mass Concentration (mg/m^3)		Mean Fibre Number (F/cm^3)			Mean Non-Fibrous Particle (nfp) (nfp/cm^3)
	Target	Achieved	Total	WHO	Fraction L > 20 μm	Total
Air control	0	0.012 ± 0.024	0.014	0	0	0.02
Carbon fibre	15	16.0 ± 1.48	1611	1046	92	888

mean = arithmetic mean
total = all objects with a 3:1 ratio (minimum) without any limits for length and diameter
WHO = fibre with a minimum in length of 5 μm and a maximum in diameter of 3 μm
fraction = number of fibre with length > 20 μm
nfp = any object with aspect ratio less than 3 was defined as a non-fibrous particle

The achieved gravimetric concentration was close to the target concentration.

Over the 5 days of inhalation exposure the variation of the carbon fibre aerosol concentration was approximately 9% demonstrating that the aerosol generation was reproducible. The variation of the carbon fibre aerosol concentration measured over the three stages of the inhalation chamber was less than 1% demonstrating that the rats attached to the different stages received the same aerosol concentration.

Aerosol Fibre Dimension

	Diameter	Length
Arithmetic Mean (μm) ± S.D.	1.04 ± 0.54	8.49 ± 7.19
Geometric Mean (μm) / G.S.D.	0.92 / 1.68	6.74 / 1.92
Median (μm)	1.0	6.4
Geometric Mean Fibres > 20 μm (μm)	1.15	28.72
% of fibres with L>20 μm	6%	

The data for samples taken during the exposure period were comparable with the dimensions of the stock material.

11.3 IN-LIFE OBSERVATIONS

Mortality data

There was no spontaneous mortality during the course of this study. All animals were sacrificed at the scheduled necropsy.

Clinical Signs

No clinical signs were observed during the course of this study, therefore no tables are included.

Body Weights

Figure, p. 32, Summary pp. 34 to 36, Individual data pp. 50 to 52.

Control animals and fibre-treated animals had similar mean body weights. No test item related effects were noted.

11.4 NECROPSY DATA

Organ Weights

Summary data: pp. 37 to 46; Individual data pp. 53 to 62.

After 29 and 92 days of recovery, lung weights including the mediastinum (absolute and relative to body weight) for group 2 (carbon fibre) were statistically significantly higher than air control. However, the weight of the lung lobes without mediastinum was only significantly increased on Day 92. It is not clear, therefore, as to whether this is treatment related since there are no increases in lung weight at the sacrifice time-points up to 29 days after the last exposure.

After 29 days of recovery absolute and relative tracheal weights for group 2 (carbon fibre) were statistically significantly higher than air control. In the absence of any statistical differences at any other time-point this finding was considered to be incidental.

Macroscopic Findings

Summary data: p. 47; Individual data pp. 63 to 68.

No macroscopical findings were noted in the control animals. Fibre-treated animals at the 1-day and the 3-day sacrifice time-points showed foci and/or not collapsed lungs. These findings were attributed to treatment since they were not present in control animals. Since there was a reduced number of animals affected at the 3-day sacrifice compared with the 1-day sacrifice and as there were no macroscopic findings at the later time-points, the observed findings were considered to reflect a minor, acute response to inhalation of particulate material.

11.5 LUNG BURDEN - CHARACTERISATION OF THE FIBRES

The table below summarises the main results for the fibre number and dimensions obtained at lung burden analysis at the successive sacrifice time points.

GSA describes the methods, the rules for fibre counting as well as the results of these analyses in the report, see Attachment 2, pp. 78 to 126. Figures of fibre clearance see pp. 26 to 31.

Group 2, CARBON FIBRE						
time point	1 day	3 days	15 days	29 days	92 days	T½ days
FIBRE NUMBER (10^6 / lung)						
Total fibres/lung	83.858	82.122	61.764	53.500	25.378	45.13s
WHO fibres/lung	51.676	48.074	37.825	33.259	15.705	50.36s
Fibres/lung < 5 µm	30.676	32.583	22.716	18.932	9.195	47.14d
Fibres/lung 5-20 µm	50.133	46.599	36.716	32.377	14.450	46.10s
Fibres/lung > 20 µm	3.049	2.940	2.332	2.191	1.734**	99.86s
Non-fibre particles	42.148	55.080	40.861	36.714	17.961	---
N=	6[1]	7	7	7	7	
DIAMETER						
Arithmetic Mean (µm)	0.96	0.96	0.99	0.98	0.99	
± S.D	0.44	0.44	0.46	0.45	0.45	
Geometric Mean (µm)	0.87	0.86	0.89	0.88	0.89	
S.D	1.59	1.61	1.60	1.59	1.59	
Median (µm)	0.9	0.9	0.9	0.9	0.9	
LENGTH						
Arithmetic Mean (µm)	7.60	7.34	7.66	7.80	8.41	
± S.D	5.47	5.34	5.67	5.68	6.67	
Geometric Mean (µm)	6.24	6.02	6.26	6.39	6.62	
± S.D	1.85	1.84	1.85	1.85	1.96	
Median (µm)	6.1	5.8	6.0	6.0	6.2	
Total length/lung (m)	637.3	603.1	473.3	417.4	213.5	49.82s
Particle/lung (10^6)	42.148	55.080	40.861	36.714	17.961	

** The number of fibres > 20µm was statistically significantly lower ($p < 0.01$) on day 92 compared with day 1.

s/d Single/double (weighted value) exponential

[1] Animal 22 was excluded because the value of the total fibre length (m), and the total number of fibres per lung, differed from the average value of all animals evaluated at the same time-point by more that two times the value of the standard deviation.

Assessment

- the overall clearance is not far above that of a biosoluble fibre
- considering the fibre size compartments, it is likely that macrophage clearance of short fibres (< 15 μm) is likely to be the most efficient mechanism
- clearance of the long fibres (> 20 μm) is less efficient. However, the decrease in the lung fibre burden (number of fibres > 20 μm at day 92 compared with day 1) was significant and likely to be caused by breakage of the long fibres into smaller ones which then are cleared by normal mechanical clearance processes (phagocytosis and removal by alveolar macrophages).

CHARACTERISATION OF
CARBON FIBRES
FROM STUDY:
3-MONTHS BIOPERSISTENCE OF FIBRES IN RATS
FOLLOWING INHALATION

Part of the RCC Study Number 801314:
CARBON FIBRE
3-Month Biopersistence Inhalation Study in the Rat.

Version: **Final Report**
Date: 11-Sept-2002

Confidentiality Statement

Contents

Summary

At RCC/Fuellinsdorf fibres were administered to rats by inhalation. As test item one type of Carbon fibres was used. The objective for GSA was to characterise the test item at different stages of the project by determining the size distribution from fibres and the fibre number concentrations. Counting and sizing were done by means of a scanning electron microscope (SEM) with energy dispersive x-ray analysis (EDS).

The investigations performed are summarised in Table 0.1 to 0.2.

Table 0.1: Test Matrix for aerosol

	Group	
	Air Control	Carbon fibre
Exposure day	Number of samples for BVA and F/cc	
1	1	1
2	1	1
3	1	1
4	1	1
5	1	1

Table 0.2: Test Matrix for Lung Burden

	Group	
	Air Control	Carbon Fibre
post-exposure day	Number of samples for BVA and F/Lung	
1	5	7
3	-	7
15	-	7
29	5	7
92	5	7

BVA = Bivariate analysis of fibre size distribution
F/cc = Determination of fibre concentration (fibre number per cubic centimetre of air)
F/Lung = Determination of fibre number per lung

The summaries of the results are given in the table 0.3 to 0.4.

Table 0.3 Air Control

Origin of sample	Sacrifice time point	Fibres L > 20 µm	WHO[1]-fibres	Total fibres		
		Number per cm^3			Geom. mean diameter [µm]	Geom. mean length [µm]
Aerosols	N.A.	0,000	0,000	0,014	1,04	3,67
Lungs		Number per lung in millions				
	1 day	0,000	0,000	0,041	1,11	5,52
	29 days	0,000	0,000	0,036	1,31	7,15
	92 days	0,000	0,000	0,082	0,79	4,22

N.A. = not applicable

[1]) WHO definition means length (L) > 5 µm, diameter (D) < 3 µm and L:D ≥ 3.

Statement of Compliance

GSA is not a GLP certified Laboratory. But GSA is

- nominated as an institute for measurements at workplace by the federal ministry of labour for sampling and counting fibres
- Co-worker in the German System for Accreditation (Deutsches Akkreditierungsystem Prüfwesen, DAP).

GSA states that, wherever possible, the investigations were conducted in compliance with:

- Grundsätze der Guten Laborpraxis [Principles of Good Laboratory Practice] (GLP), Bonn, March 22, 1990
- OECD Principles of Good Laboratory Practice, as revised in 1997 [C(97)186/(Final)].

Preface

General Information

Title:	CHARACTERISATION OF CARBON FIBRES FROM STUDY: 3-MONTHS BIOPERSISTENCE OF FIBRES IN RATS FOLLOWING INHALATION
Sponsor:	OSAKA GAS AMERICA INC. Pasadena California 91101, USA
Sponsor Representative:	Yasunobu Kikui (same address as above)
Monitoring Scientist and scientific advisor to the Sponsor:	Prof. Dr. Oberdörster 121 Southern Parkway Rochester, New York 14618, USA
Test Facility:	GSA Gesellschaft für Schadstoffmessung und Auftragsanalytik GmbH Gut Vellbrüggen D-41469 Neuss-Norf
GSA Project	RCC 801314
Test item:	Carbon fibre
Biological samples supplied by:	RCC Ltd, Toxicology Division Woelferstrasse 4 CH-4414 Fuellinsdorf RCC Ltd, Environmental Chemistry and Pharmanalytics Division Zelgliweg 1 CH-4452 Itingen

Schedule

Start of investigations:	August 2001
End of investigations:	May 2002

Archiving

GSA Neuss will archive the following data for at least ten years:
All raw data, copy of study plan, report, duplicate of report.
The remaining substance of the stock samples were stored in the archive of GSA under room conditions.
The measuring filters sampled with the suspension for SEM-analysis were stored in the archive of GSA under room conditions.
The remaining parts of the in GSA produced suspensions of the digested lung samples and the aerosol filters were stored in the archive of GSA in a refrigerator at a temperature of 5 to 8 °C until the expiration date.
Thereafter, no raw data, copy of study plan, report, duplicate of report and test item reference sample will be withdrawn without the sponsor's further consent.

At the end of 10 years (deviating from German GLP), the Sponsor will be contacted for the disposal of the archived material.
However on his request part or all archived material and documents can be sent to the Sponsor prior to the end of the 10-year period. Transportation and further archiving will occur under the responsibility of the Sponsor.

(U. Teichert)

Introduction

GSA received from RCC different kinds of samples used in the animal experiment in order to determine the fibre number concentration and/or the fibre size distribution.

Laboratory Methods

Documentation and Data Storage

For each batch of samples received from RCC a visual inspection of the parcel and of each sample container was carried out. Date and time of arrival, visual impression of the parcel's outside and inside and the identification of attached letters were recorded.
The by RCC attached chain of custody form was signed and dated. Relevant observations were noted. A copy was sent to RCC by fax in order to confirm the arrival of the samples.
For internal handling of the sample at GSA, each sample, identified with RCC-Codes, was given additionally a unique GSA-No . A block of numbers starting with 186500 was reserved for this project. For each sample an individual data sheet was prepared immediately after arriving at GSA. This sheet contains RCC and GSA sample identification, ordered analysis, dates and signatures of the persons which fulfilled the data sheet. Later on dates of preparation and analytic and signatures of the persons involved were added.

Sample Handling and Storage

Immediately after the samples were registered and the necessary analytical steps were defined, the samples were transferred into the lab together with the individual sample sheet. Suspensions were placed in a refrigerator and stored there at a temperature of less than 8 °C.
Each step of preparation and analysis as well as abnormalities, if any, in addition to the signatures of the persons involved was recorded in the individual data sheet.

General Description of Samples and Analytical Investigations

Samples

GSA received from RCC the following types of samples of the animal experiment:

a) Filters with the administered aerosols dry in a flask.

b) Filters with digested lung samples dry in flask.

Analytical Investigations

- determination of fibre number concentration in administered aerosols
- determination of fibre dimensions in administered aerosols
- determination of fibre number concentration in lungs
- determination of fibre dimensions in lungs

Analytical Methods

Sample Preparations

Aerosol Samples and digested lung samples

80 cm^3 of methanol were added to the flask containing the filters with the aerosol filters or the digested lung samples. The suspension was treated by sonication in an ultrasonic bath (35 kHz, 120 W) for 12 minutes. By doing this, the dust on the filter moved from the filter into the liquid. The filter was taken out of the flask and was washed with 10 cm^3 of methanol. This methanol was transferred back to the flask and resuspended by sonication in an ultrasonic bath (35 kHz, 120 W) for 3 minutes. An appropriate aliquot was sampled with a Gilson pipette immediately after and was diluted in 15 cm^3 of bidistilled and filtered water.

Filtration

Using a Millipore® funnel, the aqueous dispersion was filtered under moderate vacuum on a gold coated polycarbonate filter (Nuclepore®, diameter 25 mm, pore size 0.2 µm).The support filter and the measuring filter were tightly fastened into the filtration device. The filter surface was

moistened with a few drops of isopropanol. Then, as soon as the ultrasonic treatment was finished, an aliquot of the suspension was sucked into a pipette and transferred onto the filter with the addition of 1 cm^3 ethyl-alcohol. As optimum volume of the aliquot 0,5 cm^3 was judged from preliminary experiments. The liquid was sucked through the filter by means of a vacuum pump, and the solids were deposited on the surface of the filter. The ethyl-alcohol acts as an emulsifier to reduce surface tension and ensures an even distribution on the filter.

Shortly before the end of the filtration process, the inner surfaces of the filtration device above the measuring filter, which have come into contact with the suspension, were rinsed off with filtered bidistilled water from a wash bottle. The rinsing liquid was sucked through the filter together with the rest of the liquid. Finally the filter was dried in a drying chamber at 50°C without air circulation.

A report was made for each filtration. In this report all necessary data for subsequently calculating the concentration and for checking the work was recorded such as:

- designation of sample
- effective filter surface area
- volume of filtered suspension
- any special observations
- date of filtration
- name of operator

The loading of the filters with fibres and particles was checked. Only filters, whose loading allowed reliable examinations, were used. Filters too heavily loaded were rejected and a new filtration with a smaller aliquot took place. In case the filter was too poorly loaded, a new filtration with a greater aliquot was carried out.

Preparation of the filters

The gold-coated filter was fixed with conductive carbon cement, the dust loaded side up, on a filter holder of aluminium, which was pre coated with conductive carbon cement.

Determination of Fibre Dimensions

Unless otherwise specified, the basis for the evaluation using the scanning electron microscope was WHO-Reference Methods for measuring airborne man made mineral fibres (MMMF), prepared by the WHO Regional Office for Europe, Copenhagen (1985).

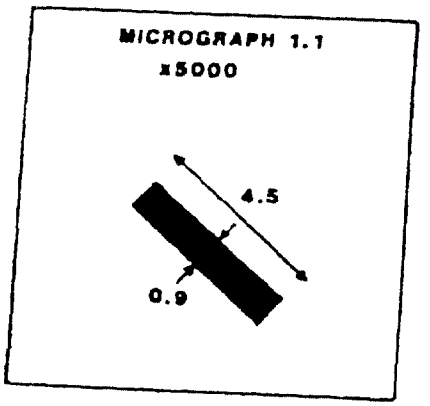
Normally the evaluation was carried out in the SEM at a magnification of 2000x. All objects which could be seen at this magnification were taken into consideration. At a magnification of 2000x the visibility is limited to fibres with a diameter of at least 0.1 µm.

The acceleration voltage was set to 25 kV.

The fields of view to be evaluated were chosen in such a way that the entire surface of the prepared filter was examined and that no overlapping of the fields of view being counted could occur.

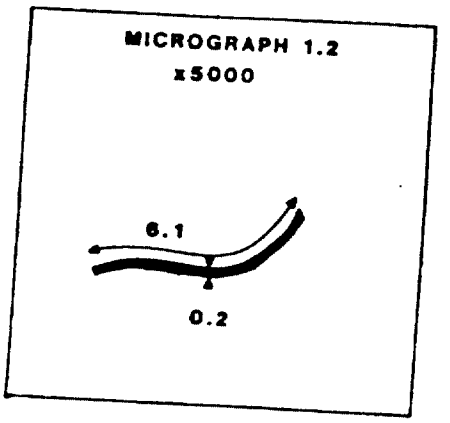
Each field of view was examined for fibres which met the criteria of length and diameter described below.

- All fibres, defined as all objects with an aspect ratio of at least 3:1, visible at a magnification of 2000x had to be taken in consideration. All fibres which were seen at this magnification were sized. No lower or upper limit was imposed on neither length nor diameter. All other objects with the same chemical composition as the fibres were defined as particles. They were measured in the same way as fibres as described below.
- Fibres with both ends in the field of view had the "weight" of one fibre (=2 fibre ends), fibres with only one end within the field had the "weight" of a half fibre (=1 fibre end). Fibres without any fibre end in the field of view had the "weight" of no fibre and were not counted nor measured.
- The number of the field of view in which the fibre was detected was recorded with the fibre "weight" and the individual bivariate length and diameter for each object measured



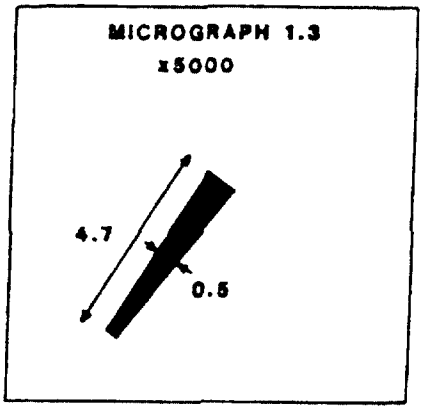
Field 1; weight 1; length 4,5 µm; diameter 0,9 µm

– Where fibres were curved, the length was measured as if the fibre were straightened out.



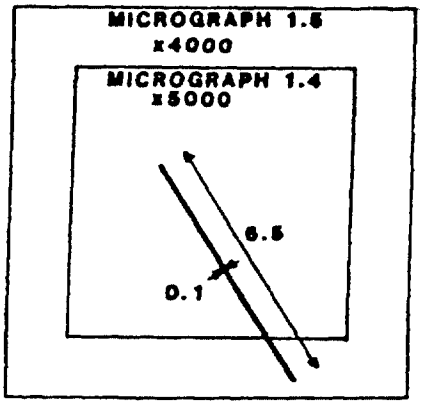
Field 2; weight 1; length 6,1 µm; diameter 0,2 µm

– Where a fibre did not have parallel sides, the diameter was measured at an "average" point.



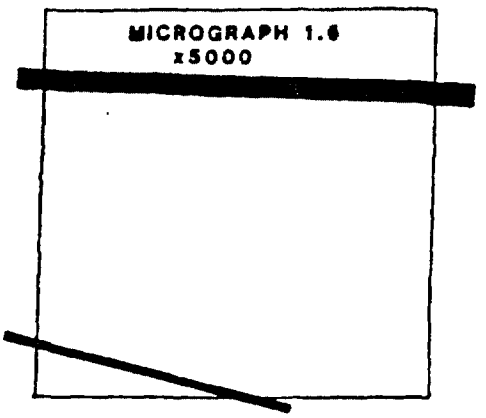
Field 3; weight 1; length 4,7 µm; diameter 0,5 µm

– If there was only one end within the field the measurements were made with a lower magnification. These measurements had the "weight" of a half fibre (one fibre end).

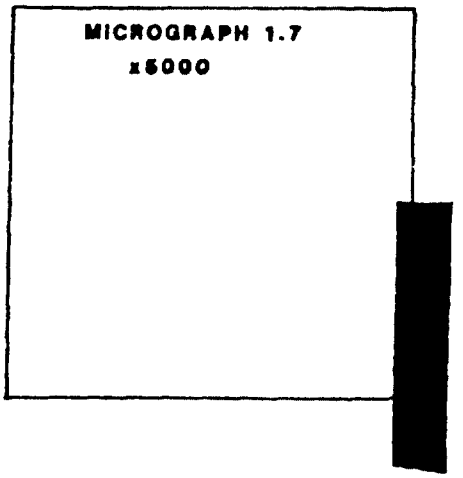


Field 4; weight 1/2; length 6,5 µm; diameter 0,1 µm

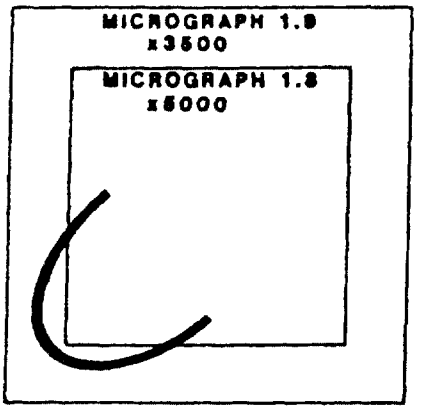
– If there were fibres with neither of there ends within the field, these fibres were not measured.



– A fibre end was defined as the midpoint of the fibre breadth at the extremity of the fibre. In the picture, the fibre end is not within the field and should not be measured.

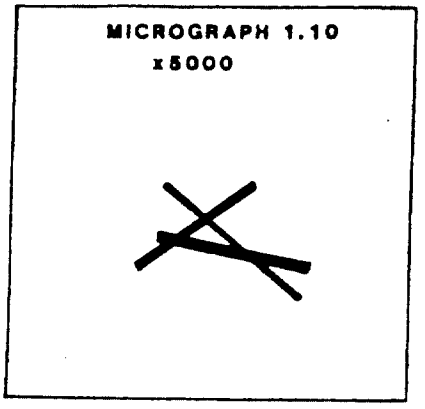


- If fibres crossed out of the field of view but have both ends within were measured and were given the weight of 1 fibre.



Field 7; weight 1; length 11 μm; diameter 0,2 μm

- Where fibres were grouped together, each constituent fibre was distinguished on the basis of continuity and measured separately.

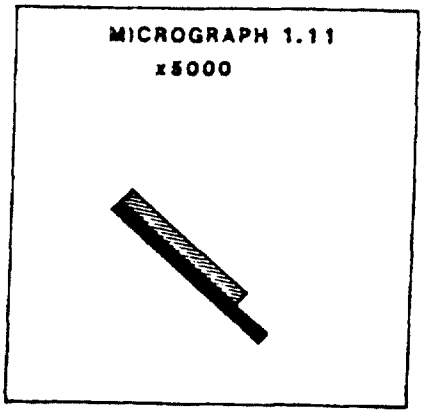


Field 8; weight 1; length 4,5 μm; diameter 0,1 μm

Field 8; weight 1; length 3,6 μm; diameter 0,2 μm

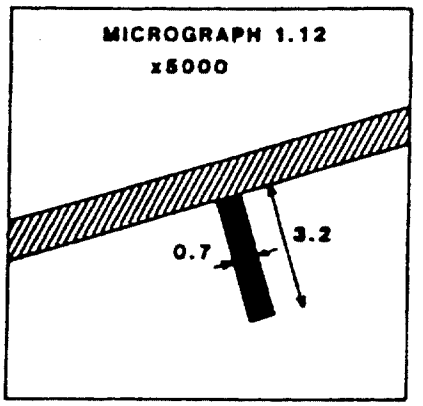
Field 8; weight 1; length 3,8 μm; diameter 0,3 μm

- In many cases, two or more fibres were seen to lie parallel to each other. Each fibre was measured.

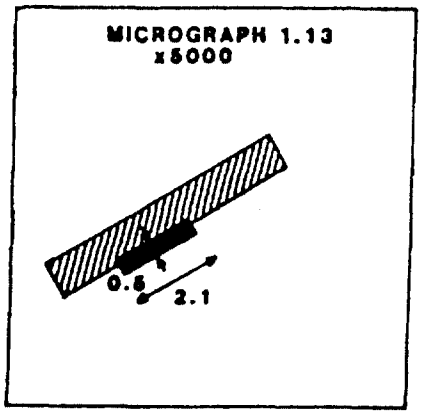


Field 9; weight 1; length 4,0 µm; diameter 0,3 µm
Field 9; weight 1; length 5,1 µm; diameter 0,3 µm

- Where two fibres were in contact, one may partially obscure the other. In these circumstances, the observed image was measured.



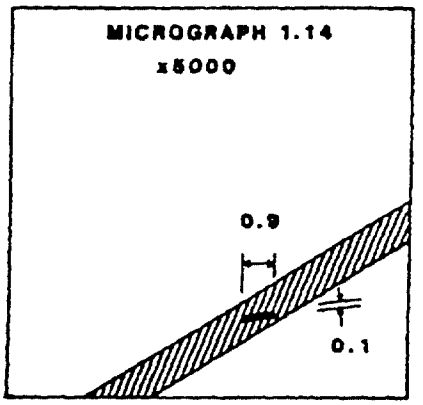
Field 10; weight 1; length 3,2 µm; diameter 0,7 µm



Field 11; weight 1; length 6,5 µm; diameter 0,9 µm

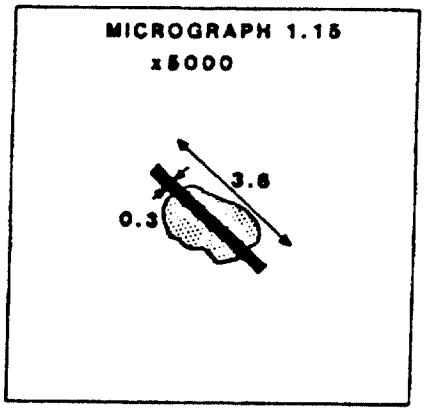
Field 11; weight 1; length 2,1 µm; diameter 0,5 µm

– In some circumstances, fibres were observed to lie directly on top of other fibres. Each fibre was measured as a distinct fibre.

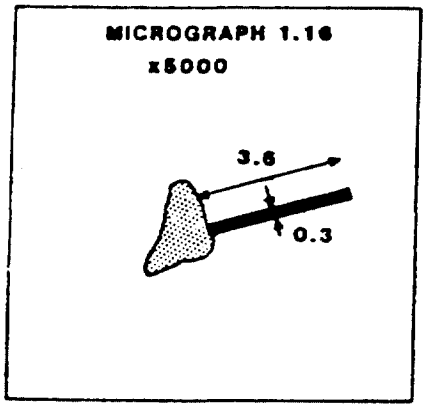


Field 12; weight 1; length 0,9 µm; diameter 0,1 µm

- Particles in contact with fibres were ignored and the visible part of the fibre was sized according to the rules given in the preceding sections. Fibres only partially obscured were measured on the basis of continuity.



Field 13; weight 1; length 3,6 µm; diameter 0,3 µm



Field 14; weight 1; length 3,6 µm; diameter 0,3 µm

The examination of the samples was stopped:

- Fibrous particles:

  So many fields of view were examined until a total of 400 WHO (length > 5 µm, diameter < 3 µm) fibres (800 fibre ends) or a total of 1000 objects was recorded or a maximum of 1 mm^2 of the filter surface was examined in case 400 countable WHO fibres was not reached.

- Non-fibrous particles:

  So many fields of view were examined until the a.m. stopping criteria for fibres were reached or a total of 100 particles were recorded.

- For samples of the control group only an area of 0,5 mm^2 of the filter was evaluated.

Sizing Report

A sizing report was set up for each sample evaluation. In this report all necessary data were recorded, such as:

- designation of sample
- effective filter surface area
- volume of filtered medium
- area of a field of view
- length and diameter of each fibre
- "weight" of each fibre
- number of fields of view in which the object was detected
- number of fields totally evaluated
- remarks in case of special observations
- date of evaluation
- name of counter

Calculation of the Fibre Number Concentration

The fibre number concentration in the suspensions was calculated from the data gained by sizing as follows:

$$C = n_{fibres} \times \frac{A_{filter}}{A_{ev}} \times \frac{1}{V_{filtered}} \qquad \text{equation (1)}$$

or

$$C = n_{fibres} \times \frac{A_{filter}}{n_{field} \times A_{screen}} \times \frac{1}{V_{filtered}} \qquad \text{equation (2)}$$

C = concentration [fibres/cm³ filtered suspension]

n_{fibres} = number of fibres sized

A_{filter} = effective filter surface area [mm²]

n_{field} = number of fields of view evaluated

A_{ev} = filter area evaluated [mm²]

A_{screen} = area of field of view [mm²]

$V_{filtered}$ = volume of filtered medium [cm³]

The number of fibres per filter was calculated as follows:

$$C_{filter} = C \times V_{meth}$$ equation (3)

C_{filter} = number of fibres on the whole original filter

V_{meth} = volume of total suspension (80+10=90 cm³)

The number of fibres per cm³ of air was calculated as follows:

$$C_{air} = C_{filter} \div V_{air}$$ equation (4)

C_{air} = fibres per cm³ of air

V_{air} = volume of air sampled

The number of fibres per lung was calculated as follows:

$$C_{lung} = C \times V_{susp}$$ equation (5)

C_{lung} = number of fibres per lung

V_{susp} = volume of total suspension (90 cm³)

$$C_{drylung} = C_{lung} / m_{drylung}$$ equation (6)

$m_{drylung}$ = weight of the dry lung (mg)

$C_{drylung}$ = number of fibres per mg dry lung

C_{lung} = number of fibres per lung

The weight of the dry lungs was determined at RCC.

Calculation of the mean fibre dimensions

The arithmetic mean diameter was calculated as follows:

$$D_{arith.\ mean..} = \Sigma D / \Sigma n \qquad \text{equation (7)}$$

ΣD =sum of all recorded diameters for each time point and fibre type
Σn =sum of all recorded fibres for each time point and fibre type

The arithmetic mean length was calculated in the same way:

$$L_{arith.\ mean..} = \Sigma L / \Sigma n \qquad \text{equation (8)}$$

ΣL =sum of all recorded lengths for each time point and fibre type
Σn =sum of all recorded fibres for each time point and fibre type

The geometric mean diameter was calculated as follows:

$$D_{geom.\ mean..} = e^{\Sigma \ln D / \Sigma n} \qquad \text{equation (9)}$$

$\Sigma \ln D$ =sum of the natural logarithm of all recorded diameters for each time point and fibre type
Σn =sum of all recorded fibres for each time point and fibre type

The geometric mean length was calculated in the same way:

$$L_{geom.\ mean..} = e^{\Sigma \ln L / \Sigma n} \qquad \text{equation (10)}$$

$\Sigma \ln L$ =sum of the natural logarithm of all recorded lengths for each time point and fibre type
Σn =sum of all recorded fibres for each time point and fibre type

The length weighted arithmetic mean diameter was calculated as follows:

$$d_{length-weightedarith.mean} = \frac{(D_1 * L_1 + D_2 * L_2 + D_3 * L_3 + ...)}{(L_1 + L_2 + L_3 + ...)} = \frac{\sum (D_i * L_i)}{\sum L_i} \qquad \text{equation (11)}$$

$\Sigma D_i * L_i$ = sum of the product of each recorded diameter and length for each time point and fibre type

ΣL_i = sum of all recorded lengths of fibres for each time point and fibre type

The length weighted geometric mean diameter was calculated as follows:

$$d_{length-weightedgeom.mean} = e^{\frac{(\ln D_1 * L_1 + \ln D_2 * L_2 + \ln D_3 * L_3 + ...)}{(L_1 + L_2 + L_3 + ...)}} = e^{\frac{\Sigma (\ln D_i * L_i)}{\Sigma L_i}} \qquad \text{equation (12)}$$

$\Sigma \ln D_i * L$ = sum of the product of each recorded natural logarithm of diameter and length for each time point and fibre type

ΣL_i = sum of all recorded lengths of fibres for each time point and fibre type

The standard deviation of the geometric mean diameter and length was calculated as follows:

$$S_{geom.mean} = e^{\sqrt{\frac{\sum (\ln D - \ln D_{geom.mean})^2}{n-1}}} \qquad \text{equation (13)}$$

ln D = natural logarithm of diameter or length

$\ln D_{geom.\ mean}$ = natural logarithm of geometric mean diameter or length

n = sum of all recorded fibres

The total length of fibres per lung was calculated as follows:

$$L_{total} = C_{lung} \times L_{mean} \qquad \text{equation (14)}$$

L_{total} = total length of fibres per lung

C_{lung} = number of fibres per lung

L_{mean} = arithmetic mean length

The mass of the fibres per lung was calculated as follows:

$$m_{fibres} = \sum \frac{D_i^2 \times \pi \times L_i}{4} \times \frac{C_{Lung}}{n} \times \delta$$

equation (15)

m_{fibres} = total mass of fibres in the lung
D_i = diameter of the individual fibre recorded
L_i = length of the individual fibre recorded
d = density of the fibre material (g/cm³)
n = sum of all recorded fibres
C_{lung} = number of fibres per lung

Statistical Analysis

Since during fibre counting the probability for non-occurrence of fibres is greater than the probability for occurrence, a Poisson-Distribution is assumed for counting statistics. For large numbers this distribution changes via a t-distribution to a normal-distribution. For the geometric parameters it was assumed that they follow a normal-distribution. Amongst arithmetic means with standard deviations, the geometric means were also calculated in order to avoid overestimation of single large numbers.

For recounts, the corresponding groups were checked for their significance using a t-test.

All given figures were rounded from the first up to the third decimal. The calculations however were done with the original figures. Therefore little differences in the sum may occur if the single values in the tables are recalculated.

Results

Fibre Number Concentrations

Aerosol Samples

The aerosol concentrations are shown in diagram 1.

More detailed information is given in Table A3 (Appended Data Tables).

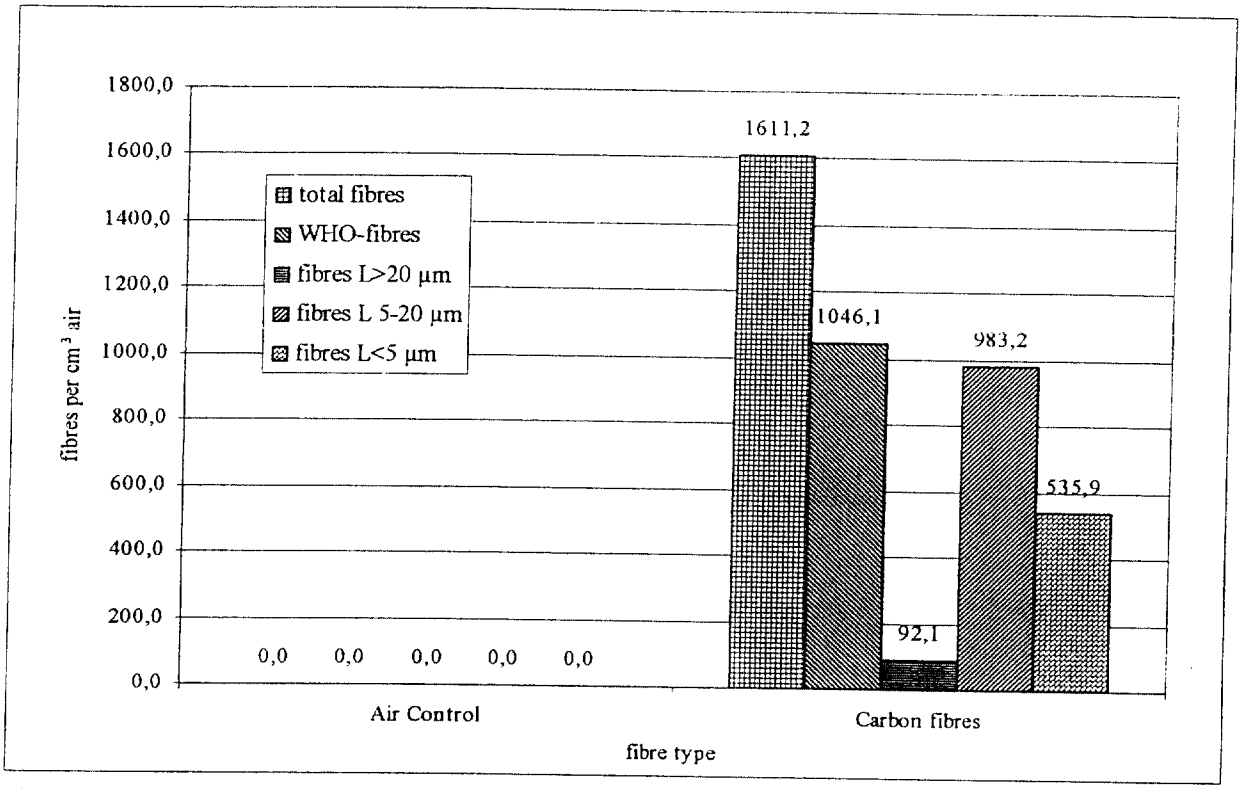


Diagram 1: Aerosol Concentrations of fibres per cm^3 of air, averaged for each design group.

- total fibres means all objects without any limit in length nor diameter but a length to diameter ratio (L:D) ≥ 3.
- WHO-fibres means the fibres with a length (L) > 5 µm, diameter (D) < 3µm and L:D ≥ 3.
- L < 5 µm means all objects with a length less than 5 µm and a length to diameter ratio (L:D) ≥ 3.
- L 5 - 20 µm means all objects with a length equal or greater than 5 µm, but not more than 20 µm, and a length to diameter ratio (L:D) ≥ 3.
- L > 20 µm means all objects with a length greater than 20 µm and a length to diameter ratio (L:D) ≥ 3.

Digested lung samples

Fibre number concentrations in millions of carbon fibres in the digested lung samples for the different sacrifice time points as for different size fractions are shown in the diagram 2. More detailed information are given in Table A5 (Appended Data Tables).

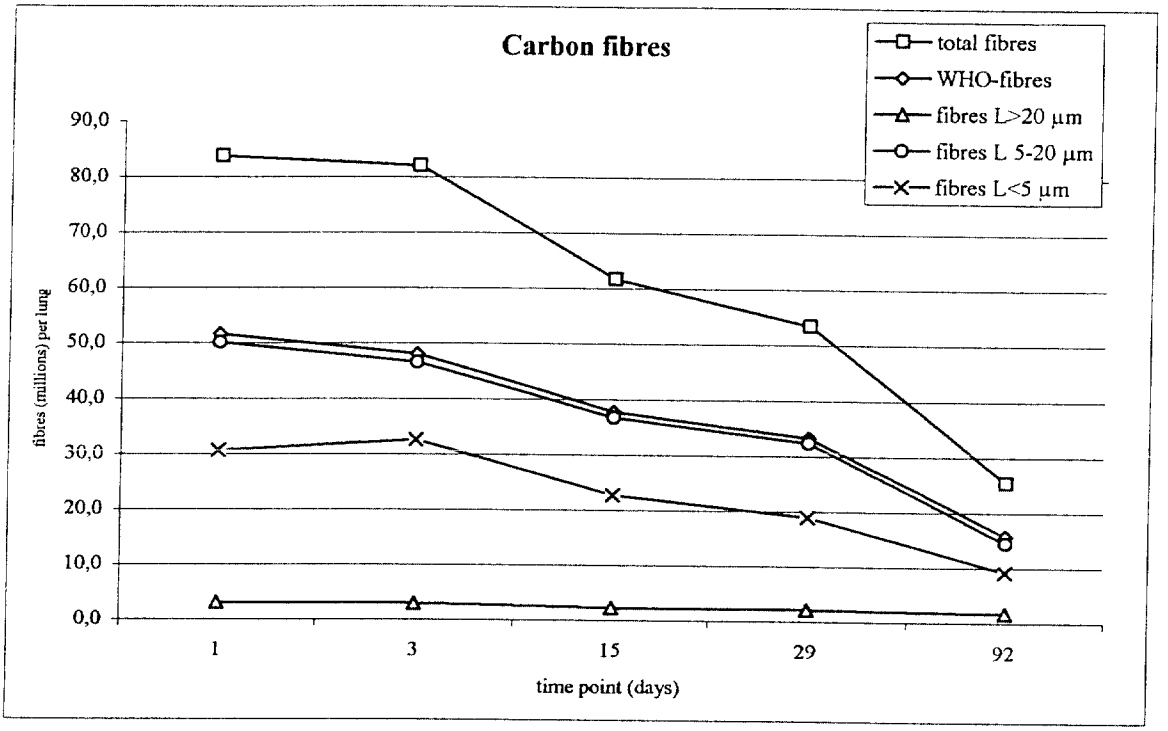

Diagram 2: Fibre number in millions of carbon fibres in the digested lung samples for sacrifice time point 1, 3, 15, 29 and 92 days for different size fractions

Fibre Dimensions

In the diagrams 3 to 10 are shown the geometric means of diameter and length and the aspect ratio for carbon fibres for aerosols and in the digested lung samples for different sacrifice time points.

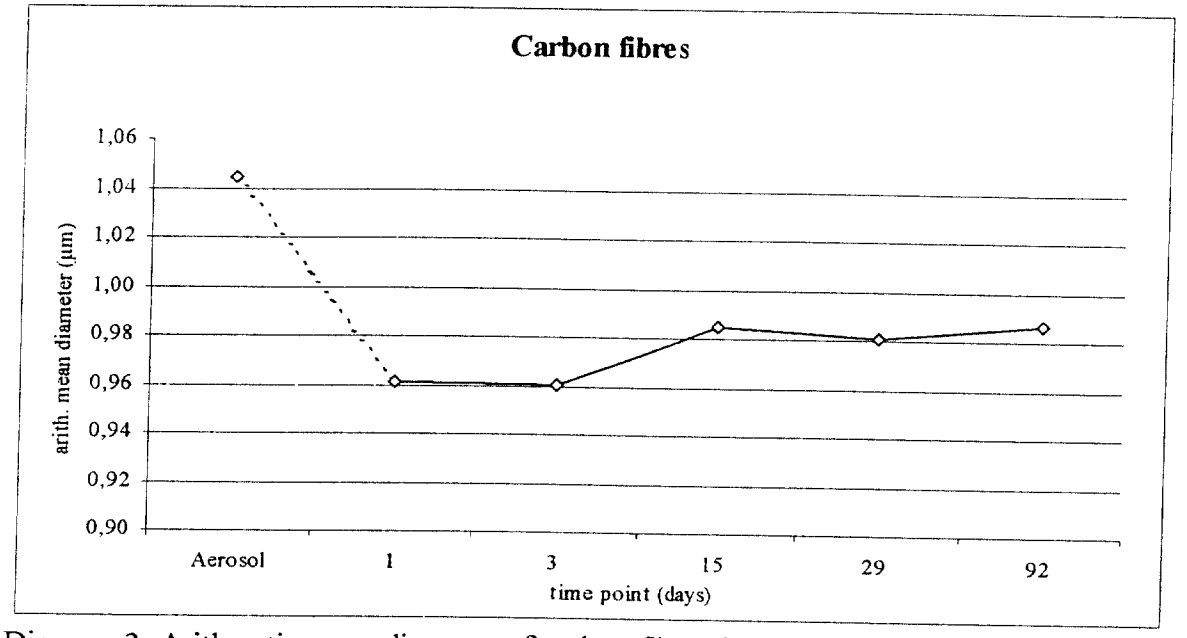

Diagram 3: Arithmetic mean diameter of carbon fibres for aerosol sample and in the digested lung samples for sacrifice time point 1, 3, 15, 29 and 92 days.

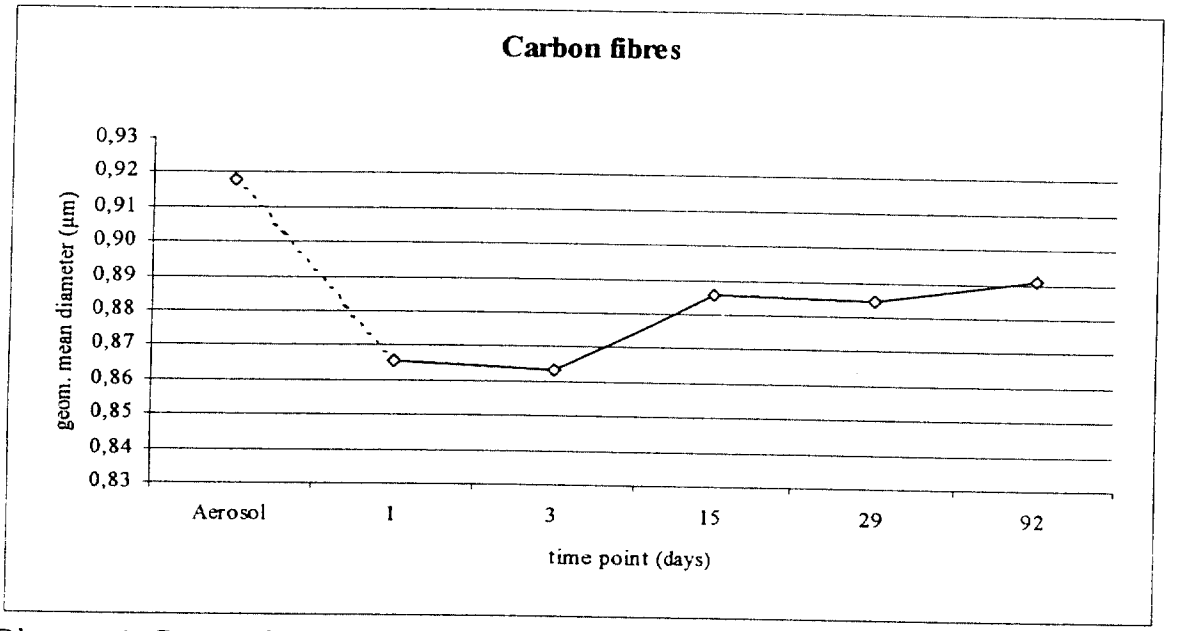

Diagram 4: Geometric mean diameter of carbon fibres for aerosol sample and in the digested lung samples for sacrifice time point 1, 3, 15, 29 and 92 days.

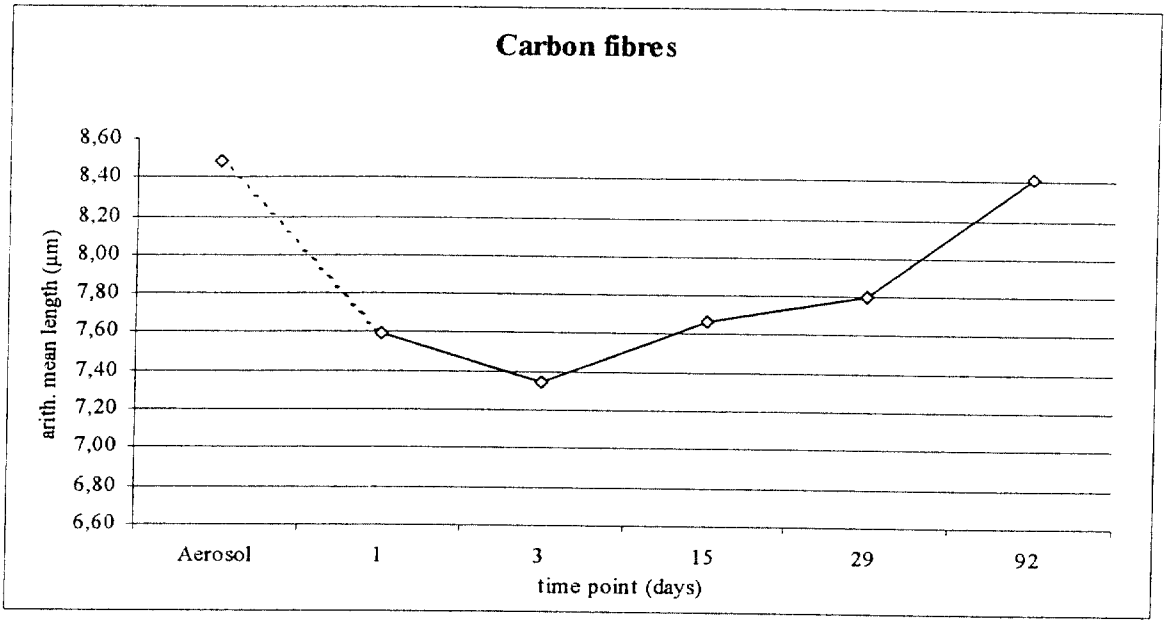

Diagram 5: Arithmetic mean length of carbon fibres for aerosol sample and in the digested lung samples for sacrifice time point 1, 3, 15, 29 and 92 days.

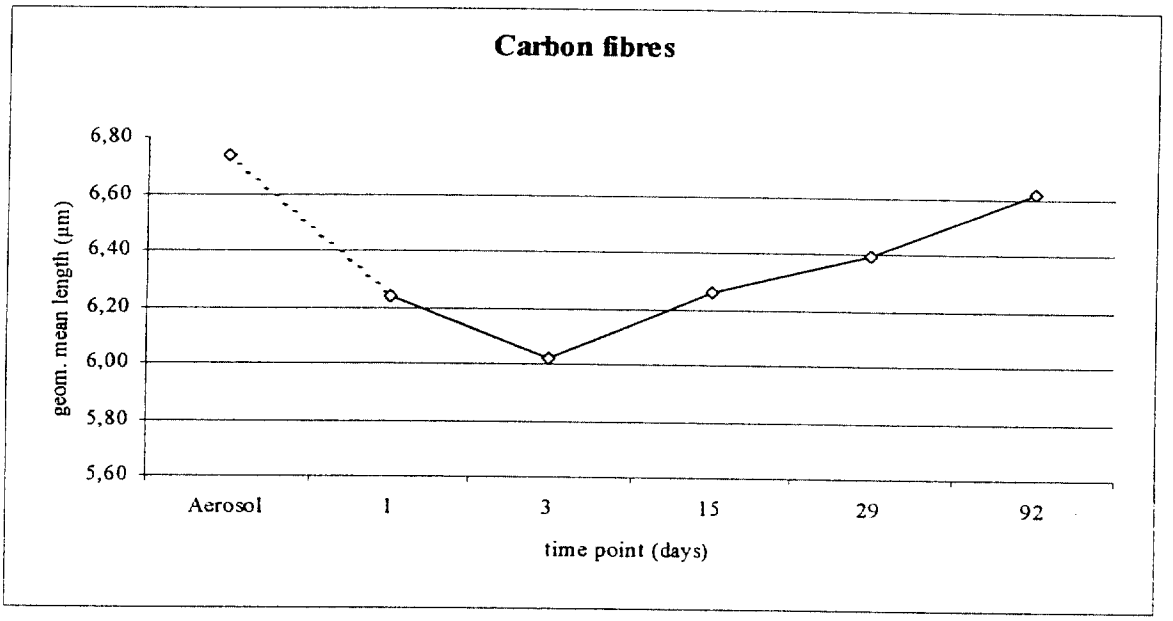

Diagram 6: Geometric mean length of carbon fibres for aerosol sample and in the digested lung samples for sacrifice time point 1, 3, 15, 29 and 92 days.

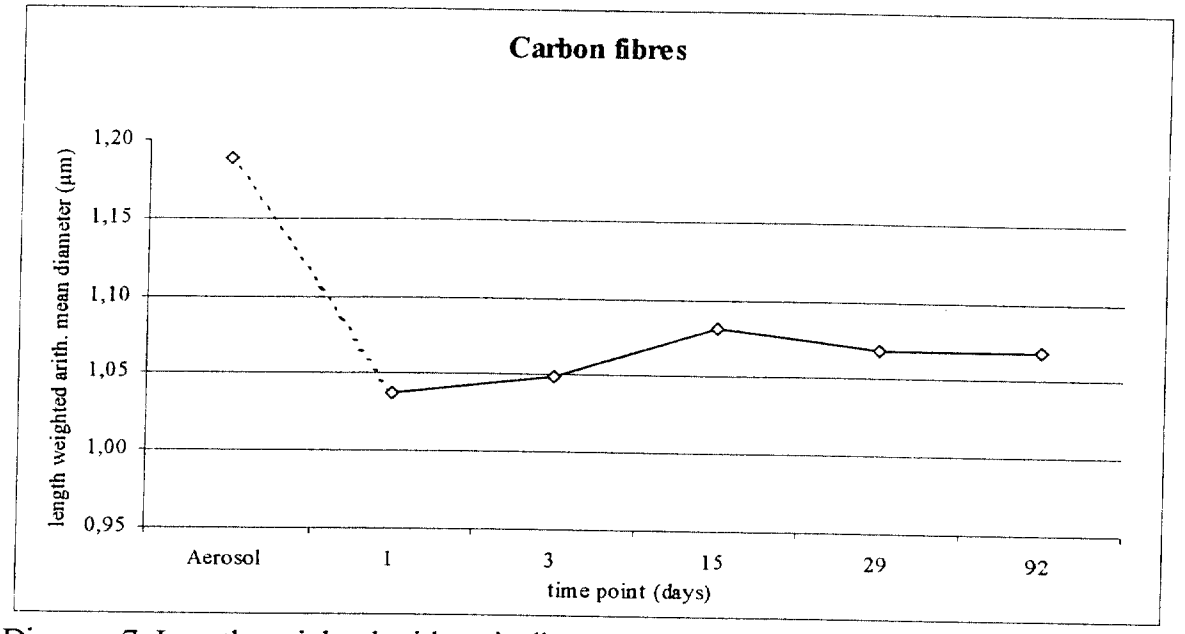

Diagram 7: Length-weighted arithmetic diameter of carbon fibres for aerosol sample and in the digested lung samples for sacrifice time point 1, 3, 15, 29 and 92 days.

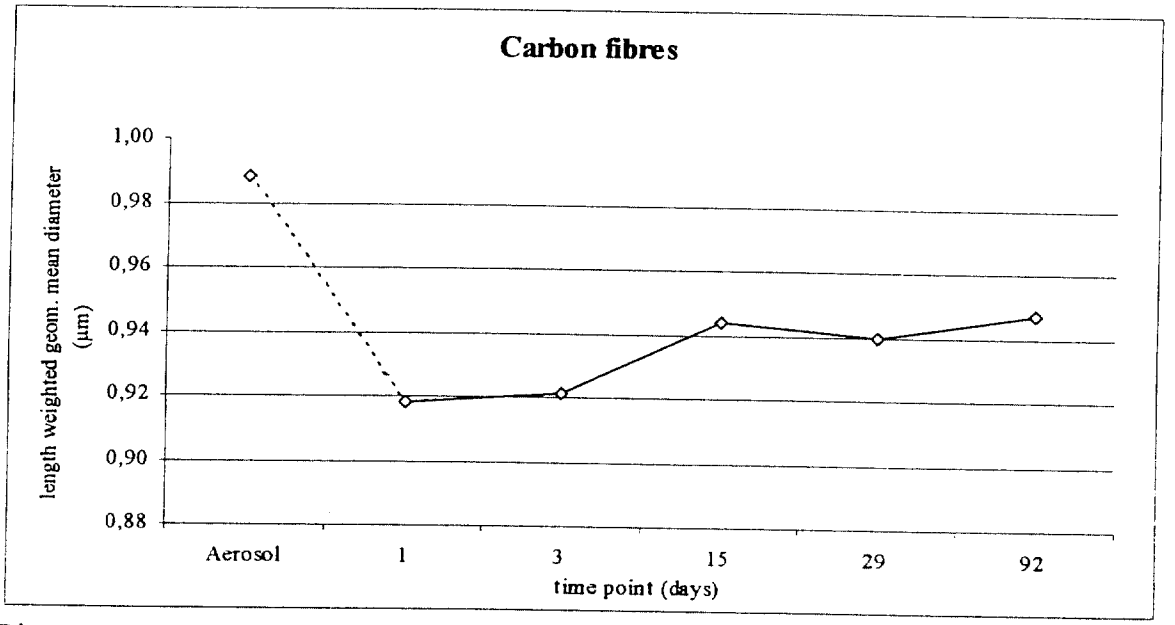

Diagram 8: Length-weighted geometric diameter of carbon fibres for aerosol sample and in the digested lung samples for sacrifice time point 1, 3, 15, 29 and 92 days.

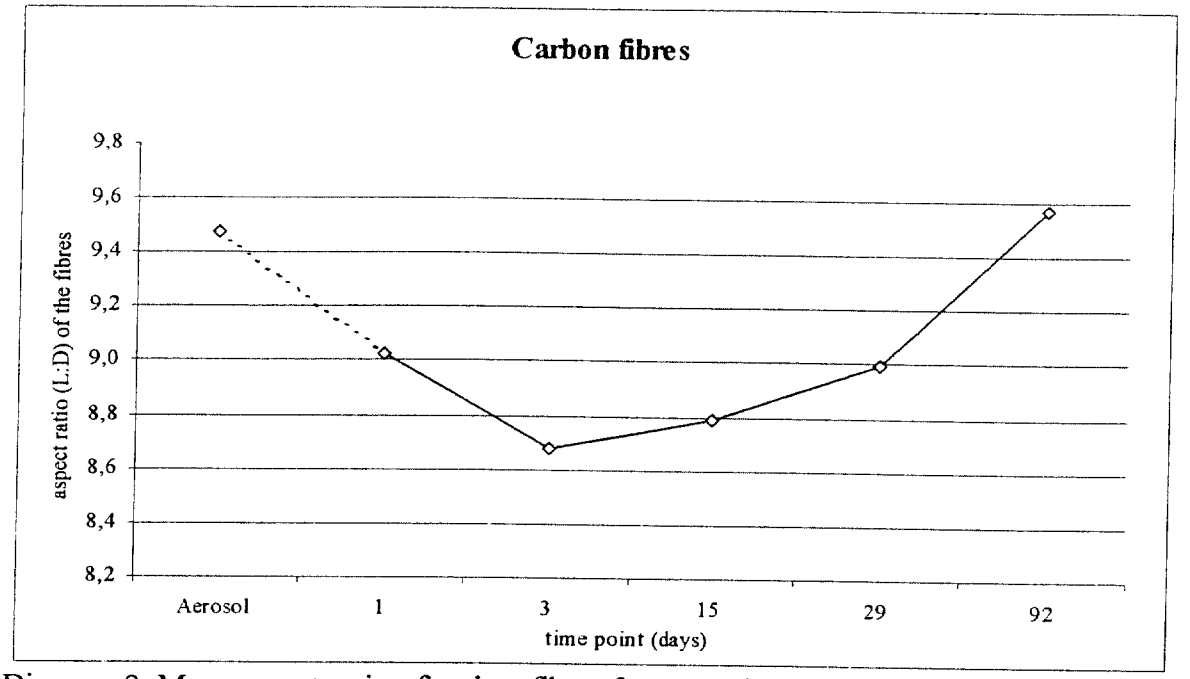

Diagram 9: Mean aspect ratio of carbon fibres for aerosol sample and in the digested lung samples for sacrifice time point 1, 3, 15, 29 and 92 days, considering length and diameter for each individual fibre.

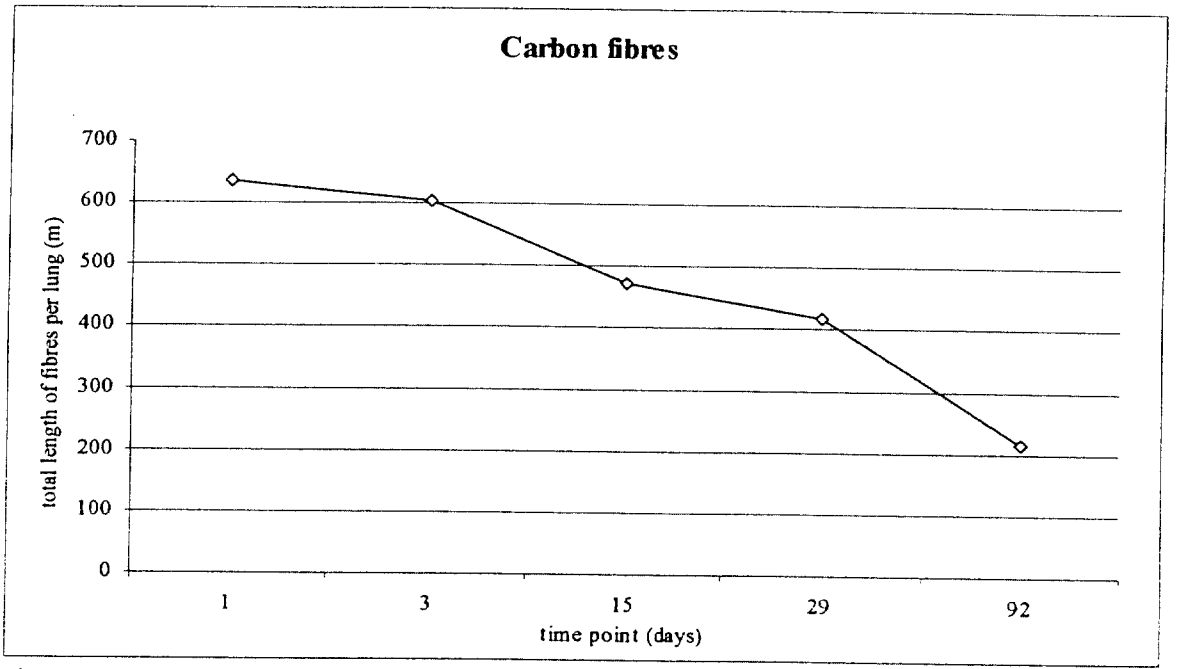

Diagram 10: Total length of fibres per lung of carbon fibres in the digested lung samples for sacrifice time point 1, 3, 15, 29 and 92 days.

More detailed information is given in tables A1 to A5 (Appended Data Tables).

Quality control

In this project about 25 thousand fibres were counted and sized. The thinnest fibre detected had a diameter of 0,1 µm. The longest fibre detected had a length of 110 µm. The average length to diameter ratio was measured in the range between 7,9 and 10,5. In these size determinations several quality assurance audits were carried out in order to verify the results. In each series of filtration the liquids used at GSA were filtered too and handled and evaluated in the SEM in the same way as RCC-samples. Totally 11 of such blank-filters were produced by filtering 20 cm^3 of the liquids through each.

In each case 1 mm^2 was evaluated. On these filters an average of 0,67 fibres/mm^2 with a standard deviation of 0,49 was found (see table 1). Since from the suspensions of the project mostly only 1 cm^3 or less was filtered, it can be assumed that during the handling at GSA the contamination was less than 2 fibres per mm^2.

One fibre detected on a blank in 1 mm^2 means 282 fibres on the whole filter, resp. 282 fibres in 90 cm^3 ***(formula 1+2).*** Since at GSA for a single sample never more than 20 cm^3 of liquids were used, 282 fibres can be assumed as background level for handling the samples at GSA.

To determine the detection limit of the method, the control samples were used. These filters contain the ash of lungs which were not exposed to fibres. ***Table 2*** shows, that the highest fibre loading was 102082 per lung which corresponds to a detection limit of 33853 fibres/lung (Poisson 95%).

STATEMENT

RCC Study Number	801314
Test Item	CARBON FIBRE
Study Director	Paul A. Smith
Title	CARBON FIBRE: 3-Month Biopersistence Inhalation Study in the Rat

This amendment to report was audited by the Quality Assurance Unit. The date is given below.

The general facilities and activities are inspected periodically and the results are reported to the responsible person and the management.

Date and Type of QAU Inspection	Date of Report to the Study Director and to Management
30-OCT-2002 Amendment to report	30-OCT-2002

This statement also confirms that this amendment to report reflects the raw data.

A

CONCERNING: **5.1 ANIMAL DATA**

PAGE: 10

PRESENT: Macroscopic findings at the 1 and 3-day sacrifice time-points indicated a minor, acute response to inhalation of a particulate material. Increased lung weights at the 29 and 92-day sacrifice time-points were observed, but it is not clear as to whether these were treatment related.

NEW: Macroscopic findings at the 1 and 3-day sacrifice time-points indicated a minor, acute response to inhalation of a particulate material. Increased lung weights at the 29 and 92-day sacrifice time-points were observed, attaining statistical significance on day 92, but it is not clear as to whether these were treatment related.

REASON FOR THE ALTERATION: Clarification of significance.

B

CONCERNING: **7.8 PATHOLOGY - Organ Sampling**

PAGE: 17

PRESENT: All freeze-dried lungs were chemically digested according to a method established at RCC and sent to GSA for lung burden investigations. The method comprised digesting the lungs in a heated acid mixture for a set duration followed by similar treatment with an oxidising agent and then vacuum filtering to trap the organic fibres on polycarbonate filters.

NEW: All freeze-dried lungs were chemically digested according to a method established at RCC and sent to GSA for lung burden investigations. The method comprised digesting the lungs in an acid mixture for two hours at 135 to 140°C, followed by similar treatment twice for 30 minutes with an oxidising agent and a cooling time between both digestions. After cooling, vacuum filtering was performed to trap the organic fibres on polycarbonate filters, remaining fibres were collected by rinsing twice the material with 1 ml Methanol and filtering the liquid on the same polycarbonate filter.

This method was developed and carefully validated at RCC. During pretests, lungs were spiked with a known amount of test item in order to monitor the recovery of unbroken fibres. The digestion method showed that the lung tissue was well eliminated without changing the fibre morphology and that recovery of the carbon fibre was good.

REASON FOR THE ALTERATION: Specification of the digestion procedure on request by the Sponsor.

5 SUMMARY

The purpose of this study was to assess the in-vivo pulmonary biopersistence of inhaled fibrous and non-fibrous particles in the rat following repeated inhalation exposure.

Laboratory rats were randomly assigned to one negative control group and to one group exposed to the test item, Carbon Fibre. The animals were exposed to filtered air (negative control) or to well characterised fibres which were sized to be rat respirable using a flow past, nose only exposure system. In the fibre-exposed group, the concentration was targeted to 15 mg/m^3 if technically feasible. The achieved concentration was 16 mg/m^3. The rats were exposed for five consecutive days, 6 hours per day, with a subsequent non-exposure period. In the control and in the fibre-exposed groups, rats were allocated to sub-groups of 5 and 7 animals respectively and sacrificed at 1 day, 3 days, 15 days, 29 days and 92 days.

For each of the sacrifice time-points the lung burden was determined by suitable extraction and measurement methods. Evaluation included counting of the number of fibres and particles in the lungs and characterisation of the fibres by bivariate analysis of diameter and length.

5.1 ANIMAL DATA

The in-life data recorded during the study - mortality, clinical signs and body weights - gave no indications of fibre-related findings.

Macroscopic findings at the 1 and 3-day sacrifice time-points indicated a minor, acute response to inhalation of a particulate material. Increased lung weights at the 29 and 92-day sacrifice time-points were observed, attaining statistical significance on day 92, but it is not clear as to whether these were treatment related.

5.2 LUNG BURDEN DATA

The main results of lung burden analyses by SEM performed at GSA are summarised below. Details are presented in Attachment 2.

Group 2, CARBON FIBRE						
time point	**1 day**	**3 days**	**15 days**	**29 days**	**92 days**	**T ½ days**
FIBRE NUMBER (10^6 / lung)						
Total fibres/lung	83.858	82.122	61.764	53.500	25.378	45.13s
WHO fibres/lung	51.676	48.074	37.825	33.259	15.705	50.36s
Fibres/lung < 5 µm	30.676	32.583	22.716	18.932	9.195	47.14d
Fibres/lung 5-20 µm	50.133	46.599	36.716	32.377	14.450	46.10s
Fibres/lung > 20 µm	3.049	2.940	2.332	2.191	1.734**	99.86s
Total length of fibres/lung (m)	637.3	603.1	473.3	417.4	213.5	49.82s
Non-fibre particles	42.148	55.080	40.861	36.714	17.961	---
N=	6*	7	7	7	7	

* Animal 22 was excluded because the value of the total fibre length (m), and the total number of fibres per lung, differed from the average value of all animals evaluated at the same time-point by more that two times the value of the standard deviation.

** The number of fibres > 20µm was statistically significantly lower ($p < 0.01$) on day 92 compared with day 1.

s Single exponential

d double exponential (weighted value)

Organ Sampling

All action was taken to avoid contamination of the dissected specimen by fibres from the fur or deposited on dissecting instruments. Special care was taken to avoid inter-group contamination. During each necropsy session, air control animals were dissected first.

For each animal the following procedure was followed:

- **The lungs and trachea** (sectioned below the larynx) were removed with the attached mediastinal tissue. The mediastinal tissue containing the mediastinal lymph nodes was resected and immediately deep-frozen on dry ice and then stored at -20°C or below, at RCC for possible investigations prescribed by the Sponsor under separate contractual agreement. However, if not used, storage of these specimens ends by the time of submission of the final report. The remaining tissue/organs: lower half of the trachea, main stem bronchi and lungs were weighed (recorded as "lung weight").
- **The trachea and the main stem bronchi** down to the limit of the lung lobes were resected in one piece, weighed (recorded as "trachea"), individually inserted into plastic bags appropriately labelled and immediately deep-frozen on dry ice and then stored at -20°C or below, at RCC for possible investigations prescribed by the Sponsor under separate contractual agreement. However, if not used, storage of these specimens ends by the time of submission of the final report.
- **All lung lobes** were weighed together (recorded as "all lung lobes"), immediately deep-frozen on dry ice and forwarded (deep-frozen) to RCC ECP (attn: M. Kern). The lungs were freeze dried, weighed (recorded as "dry lung weight"), inserted into a plastic bag appropriately labelled, then stored in a desiccator at room temperature until further processing.

All freeze-dried lungs were chemically digested according to a method established at RCC and sent to GSA for lung burden investigations. The method comprised digesting the lungs in an acid mixture for two hours at 135 to 140°C, followed by similar treatment twice for 30 minutes with an oxidising agent and a cooling time between both digestions. After cooling, vacuum filtering was performed to trap the organic fibres on polycarbonate filters, remaining fibres were collected by rinsing twice the material with 1 ml Methanol and filtering the liquid on the same polycarbonate filter.

This method was developed and carefully validated at RCC. During pretests, lungs were spiked with a known amount of test item in order to monitor the recovery of unbroken fibres. The digestion method showed that the lung tissue was well eliminated without changing the fibre morphology and that recovery of the carbon fibre was good.
